# NATURAL HISTORY

AMERICAN MUSEUM OF NATURAL HISTORY, NEW YORK, N.Y.

## INDEX TO VOLUME 89, 1980

### AUTHORS AND TITLES

A

Adey, W.H., *Review*, Feb., p. 82
Andrews, R.C., *The Fate of the Rash Platybelodon*, Apr., p. 78
Anthony, H.E., *Can We Save the Mammals?* Apr., p. 106
Appleby, L.G., *Snakes Shedding Skin*, Feb., p. 64
Arbib, R., *Review*, Dec., p. 78
Aris, M., *Sacred Dances of Bhutan*, Mar., p. 38
Armelagos, G., *The Food Connection*, Sept., p. 26

B

Barker, A.D., *Over the South Pole by Air*, Apr., p. 114
Beckwith, C., *Warriors of Maasailand*, Aug., p. 42
Berger, A.K., *Mounting Horse Skeletons to Exemplify Different Gaits and Actions*, Apr., p. 100
Bibikov, D.I., *Wolves in the USSR*, June, p. 58
Blackman, M.B., *Posing the American Indian*, Oct., p. 68
Bockstoce, J., *Battle of the Bowheads*, May, p. 52
Boltin, L., *Impressions of Traditional Asia*, Sept., p. 46
Bordaz, J., and L.A., *The Versatile Opium Poppy*, Oct., p. 52
Bourgeois, J.-L., *Welcoming the Wind*, Nov., p. 70
Bryson, R.A., *Ancient Climes on the Great Plains*, June, p. 64
Butler, J.N., *Pink Stripe on the Ocean*, July, p. 62
Byrd, R.E., *Over the South Pole by Air*, Apr., p. 114

C

Carpenter, E., *If Wittgenstein Had Been an Eskimo*, Feb., p. 72
Carson, G., *Jefferson Davis's Camel Corps*, May, p. 70; *Review*, Nov., p. 92
Carter, T.S., *Giant Anteaters*, Oct., p. 62
Chapman, F.M., *The European Starling as an American Citizen*, Apr., p. 60
Cockerell, T.D.A., *The Troublesome Notion of Evolution*, Apr., p. 118
Conklin, E.G., *The Troublesome Notion of Evolution*, Apr., p. 118
Cook, R.E., *Reproduction by Duplication*, Mar., p. 88
Coppinger, L., and R., *So Firm a Friendship*, Mar., p. 12
Cracraft, J., *Moas and the Maori*, Oct., p. 28

D

Dart, R.A., *Taungs and its Significance*, Apr., p. 66
Denys, C.J., *The High Importance of the Lowly Krill*, Mar., p. 66
Desowitz, R.S., *The Worm-Asthma Controversy*, June, p. 20
Dubos, R., *Nutritional Ambiguities*, July, p. 14

E

Eberhard, W.G., *Spider and Fly Play Cat and Mouse*, Jan., p. 56
Eldredge, N., *An Extravagance of Species*, July, p. 46
Ellsworth, L., *North to 88 and the First Crossing of the Polar Sea*, Apr., p. 20
Emiliani, C., *Ice Sheets and Ice Melts*, Nov., p. 82

F

Fairservis, W.A., Jr., *Impressions of Traditional Asia*, Sept., p. 46
Farb, P., *Review*, May, p. 84; *The Food Connection*, Sept., p. 26
Fisher, C., *The Hayden Planetarium*, Apr., p. 31; *The New Planet*, Apr., p. 50
Freed, R.S. and S.A., *Origin of the Swastika*, Jan., p. 68
Frisch, R.E., *Fatness, Puberty, and Fertility*, Oct., p. 16

G

Geist, V., *Downtown Deer*, Mar., p. 56
Gerlach, L.P., *You and the Ecology Movement*, July, p. 6; *Terrible Questions Provoke Great Responses*, Nov., p. 30
Gerson, C.D., *Dietary Fiber and Animal Fat*, Nov., p. 96
Ghani, A., *Afghanistan's Sorrow and Pity*, July, p. 64
Gmelch, G. and S.B., *Ireland's Bountiful Bogs*, Nov., p. 48
Gould, S.J., *Wallace's Fatal Flaw*, Jan., p. 26; *In the Midst of Life . . .*, Feb., p. 34; *Death before Birth*, Mar., p. 32; *Dr. Down's Syndrome*, Apr., p. 142; *The First Forebear*, May, p. 20; *The Belt of an Asteroid*, June, p. 26; *Hen's Teeth and Horse's Toes*, July, p. 24; *The Piltdown Conspiracy*, Aug., p. 8; *Vision with a Vengeance*, Sept., p. 16; *Hopeful Monsters*, Oct., p. 6; *Chance Riches*, Nov., p. 36; *Science and Jewish Immigration*, Dec., p. 14
Grabau, A.W., *The Troublesome Notion of Evolution*, Apr., p. 118
Gregory, W.K., *The Loch Ness "Monster,"* Apr., p. 130
Grinnell, G.B., *A Chapter of History and Natural History in Old New York*, Apr., p. 94
Groce, N., *"Everyone Here Spoke Sign Language,"* June, p. 10

H

Haber, G.C., *The Balacing Act of Moose and Wolves*, Oct., p. 38
Haimson, L., *The Comet Syndrome*, Dec., p. 54
Hallett, J., *When Hail Breaks Loose*, June, p. 54

Hamilton, R.M., *Quakes Along the Mississippi*, Aug., p. 70
Hanken, J., *Salamander Invasion of the Tropics*, Dec., p. 46
Harvey, H.R., *Review*, Aug., p. 84
Harwood, M., *Review*, July, p. 82
Heinrich, B., *Artful Diners*, June, p. 42
Henry, J.D., *Fox Hunting*, Nov., p. 60
High, C., *New England Returns to Wood*, Feb., p. 14
Hine, V., *You and the Ecology Movement*, July, p. 6
Hunt, R.H., *Toad Sanctuary in a Tarantula Burrow*, Mar., p. 48

**I**

Ingersoll, A.P., *By Jove*, May, p. 62

**J**

Johnsgard, P.A., *Where Have All the Curlews Gone?* Aug., p. 30
Johnson, J., *The Balancing Act of Moose and Wolves*, Oct., p. 38
Jones, J.H., *Desert Shrewd*, Jan., p. 46
Jordan, D.S., *The Troublesome Notion of Evolution*, Apr., p. 118

**K**

Kennedy, M.K., *Horse and Buggy Island*, May, p. 34
Krasemann, S.J., *Fox Hunting*, Nov., p. 60
Kricher, J.C., *Needs of Weeds*, Dec., p. 36
Kugelmass, J.M., *The Miracle of Intervale Avenue*, Dec., p. 26
Kurin, R., *Doctor, Lawyer, Indian Chief*, Nov., p. 6

**L**

LeCroy, M., *Review*, Jan., p. 94
Lee, D.S., *The Pocket Gopher Mound Probe*, June, p. 36
Levy, Y., *The Miracle of Intervale Avenue*, Dec., p. 26
Lewis, H.T., *Indian Fires of Spring*, Jan., p. 76
Lindstedt, S.L., *Desert Shrewd*, Jan., p. 46
Love, M., *The Alien Strategy*, May, p. 30; *Oh Sex, Where Is Thy Sting?* Nov., p. 26
Lynch, J.F., *Salamander Invasion of the Tropics*, Dec., p. 46

**M**

MacBean, J.R., *Review*, Apr., p. 158
Maran, S.P., *A Star in Trouble*, Jan., p. 86; *Quasars Confirmed*, Feb., p. 78; *Two Satellites in Search of X-rays*, Mar., p. 78; *The Orion Nebula*, May, p. 80; *Telescope in Space*, July, p. 86; *Far-out Erupting Volcanoes*, Sept., p. 88; *A New Supernova*, Oct., p. 76; *The Gamma Ray Mystery*, Nov., p. 108
Matthew, W.D., *The Troublesome Notion of Evolution*, Apr., p. 118
McNulty, F., *Review*, June, p. 82
McWhinnie, M.A., *The High Importance of Lowly Krill*, Mar., p. 66
Mead, J.I., *In Search of Ancient Pack Rats*, Sept., p. 40
Mead, M., *Samoan Children at Work and Play*, Apr., p. 103
Mendez, R.A., *Desert Shrewd*, Jan., p. 46; *The Pocket Gopher Mound Probe*, June, p. 36
Merritt, R.W., *Horse and Buggy Island*, May, p. 34
Moll, D., *Dirty River Turtles*, May, p. 42
Mulholland, J.D., *The Chandler Wobble*, Apr., p. 134

**N**

Netboy, A., *Those Salmon Keep Butting Those Dams*, July, p. 52
Nicholson, T.D., *Celestial Events*, Jan., p. 90; Feb., p. 94; Mar., p. 86; Apr., p. 132; May, p. 76; June, p. 74; July, p. 80; Aug., p. 78; Sept., p. 96; Oct., p. 80; Nov., p. 106; Dec., p. 76

**O**

Oppenheimer, M., *The Comet Syndrome*, Dec., p. 54
Osborn, H.F., *Can We Save the Mammals?* Apr., p. 106; *Alfred Russel Wallace 1823–1913*, Apr., p. 119
Otte, D., *Beetles Adorned with Horns*, Aug., p. 34
Owens, D. and M., *Hyenas of the Kalahari*, Feb., p. 44

**P**

Parsons, K.E., *A Fish with Double Vision*, Jan., p. 62
Playford, P.E., *Australia's Stromatolite Stronghold*, Oct., p. 58
Powell, D.E., *Review*, Oct., p. 92

**R**

Radcliffe, B., *You and the Ecology Movement*, July, p. 6; *Terrible Questions Provoke Great Responses*, Nov., p. 30
Reeds, C.A., *The Japanese Earthquake Explained*, Apr., p. 72
Roosevelt, T., *My Life as a Naturalist*, Apr., p. 84
Rubin, V.C., *Galactic Go-around*, Aug., p. 80

**S**

Saitoti, T.O., *Warriors of Maasailand*, Aug., p. 42
Shaw, J.H., *Giant Anteaters*, Oct., p. 62
Simpson, L.L., *Deadly Botulism*, Jan., p. 12
Smith, R.L., *Daddy Water Bugs*, Feb., p. 56
Sokolov, R., *Tasty Pasty*, Jan., p. 100; *Moses and Manhasset*, Feb., p. 102; *The Giant Snail of La Jolla*, Mar., p. 102; *Morel Victory*, Apr., p. 166; *In Search of a Proper Tillamook*, May, p. 96; *An Original Old-fashioned Yankee Clambake*, June, p. 96; *Stalking the Cultivated Gooseberry*, July, p. 96; *Hot Cajun Sausage*, Aug., p. 92; *A Squirrel in Every Pot*, Sept., p. 100; *Fleece Afoot*, Oct., p. 94; *The Independence Fair*, Nov., p. 114; *White Lightning*, Dec., p. 86
Stevens, J.K., *A Fish with Double Vision*, Jan., p. 62
Susman, R., *Acrobatic Pgymy Chimpanzees*, Sept., p. 32
Swain, W.R., *The World's Greatest Lakes*, Aug., p. 56

**T**

Tim, S.K.-M., *Review*, Sept., p. 78
Turnbull, C., *Christmas in Jerusalem*, Dec., p. 20

**V**

Van Gelder, R., *Malaria Safari*, May, p. 10

**W**

Wake, D.B., *Salamander Invasion of the Tropics*, Dec., p. 46
Welsch, R.L., *No Fuel Like an Old Fuel*, Nov., p. 76
Whyte, W.H., *Street Life*, Aug., p. 62
Wilson, G.L., *The Ordeal of Getting Civilized*, Apr., p. 40
Winick, M., *Nutrition and Brain Development*, Dec., p. 6

## SUBJECT MATTER

Abalone, Mar., p. 103
Afghanistan, July, p. 64
Africa, Kalahari Desert, Feb., p. 44
**AIRS, WATERS, AND PLACES**
  Asthma hypothesis, June, p. 20
  Nutrition and cancer, Nov., p. 96
Alfred Russel Wallace 1823–1913, Apr., p. 119
Algae, stromatolite, Oct., p. 58
Americana, Jefferson Davis's camel corps, May, p. 70
**AMERICAN INDIANS**
  Canadian, Jan., p. 76
  Photography, Oct., p. 68
  Ways of, Apr., p. 40
Anteaters, giant, Oct., p. 62
**ANTHROPOLOGY**
  American Indians, Jan., p. 76; Apr., p. 40; Oct., p. 68
  Asia, Sept., p. 46
  Bhutan dances, Mar., p. 38
  Eskimo carvings, Feb., p. 72
  Maasai, Aug., p. 42
  Punjabi villagers, Nov., p. 6
  Samoa, Apr., p. 103
  Swastika, Jan., p. 68
  Turkey, poppy village, Oct., p. 52
Apes, pygmy chimpanzees, Sept., p. 32
**ARCHEOLOGY**
  Ireland bogs, Nov., p. 48
**ART**
  Eskimo carvings, Feb., p. 72
Asia, Sept., p. 46

steroid, June, p. 26
sthma, June, p. 20
STRONOMY
  Asteroid, June, p. 26
  Celestial Events, Jan., p. 90; Feb., p. 94; Mar., p. 86; Apr., p. 132; May, p. 76; June, p. 74; July, p. 80; Aug., p. 78; Sept., p. 96; Oct., p. 80; Nov., p. 106; Dec., p. 76
  Earth's axis, Apr., p. 134
  Gamma ray, Nov., p. 108
  Hayden Planetarium, Apr., p. 31
  Jupiter moon Io, Sept., p. 88
  Orbiting observatory, July, p. 86
  Orion nebula, May, p. 80
  Planets, Apr., p. 50
  Quasars, Feb., p. 78
  Satellites, Mar., p. 78
  Sky Reporter, Jan., p. 86; Feb., p. 78; Mar., p. 78; Apr., p. 134; May, p. 80; July, p. 86; Aug., p. 80; Sept., p. 88; Oct., p. 76; Nov., p. 108
  Spiral galaxies, Aug., p. 80
  Star SS433, Jan., p. 86
  Supernova, Oct., p. 76
  *Voyager,* May, p. 62
Astrophysics, July, p. 86
At the American Museum, Jan., p. 92; Feb., p. 96; Mar., p. 74; Apr., p. 150; May, p. 90; June, p. 76; July, p. 90; Aug., p. 90; Sept., p. 84; Oct., p. 82; Nov., p. 112; Dec., p. 62
Australia, Oct., p. 58
Bhutan, sacred dances, Mar., p. 38
BIOLOGY
  Parasites, May, p. 30
BIRDS
  Eskimo curlews, Aug., p. 30
  European starlings, Apr., p. 60
  Extinct, Oct., p. 28
  Hens, July, p. 24
BOTANY
  Algae, Oct., p. 58
  Plant cloning, Mar., p. 88
  Poppy, Oct., p. 52
Botulism, Jan., p. 12
Brunswick stew and burgoo, Sept., p. 100
Buffalo chips, Nov., p. 76
Camel, May, p. 70
CANADA
  American Indians, Jan., p. 76
  Forests, Jan., p. 76
Caterpillars, June, p. 42
Celestial Events *see* Astronomy
Cheddar cheese, May, p. 96
Chips, cow and buffalo, Nov., p. 76
City life, Aug., p. 62
Clambake, June, p. 96
Communication, sign language, June, p. 10
CONSERVATION
  Mammals, Apr., p. 106
  Theodore Roosevelt, Apr., p. 84
Cow chips, Nov., p. 76
CRUSTACEANS
  Antarctica krill, Mar., p. 66
  Giant snail, Mar., p. 102
Curlews, Eskimo, Aug., p. 30
Deafness, June, p. 10
Deer, mule, Mar., p. 56
Deformed birth, Oct., p. 6
DESERT
  Kalahari, Feb., p. 44
  Shrew, Jan., p. 46
*D. fuscus*, Jan., p. 62
Diet, July, p. 14
Disease, botulism, Jan., p. 12
Dogs, sheep, Mar., p. 12
Down's syndrome, Apr., p. 142
EARTHQUAKES
  Japan, April, p. 72
  Mississippi Valley, Aug., p. 70
ECOLOGY
  Antarctica crustacea, Mar., p. 66
  Food connection, Sept., p. 26
  Movement, July, p. 6
  Questionnaire, Nov., p. 30
  River turtles, May, p. 42
ENDANGERED SPECIES
  Antarctica krill, Mar., p. 66
  Salmon, July, p. 52
  Whales, May, p. 52
ENERGY
  Cow and buffalo chips, Nov., p. 76
  Ireland bogs, Nov., p. 48
  Wind, Nov., p. 70
  Wood, Feb., p. 14
ENVIRONMENT
  Canadian forests, Jan., p. 76
  Lakes, Aug., p. 56
ESKIMOS
  Carvings, Feb., p. 72
  Curlews, Aug., p. 30
  and Whales, May, p. 52
EVOLUTION
  Birds, Oct., p. 28
  Human, Sept., p. 16, p. 32
  Piltdown skull, Aug., p. 8
  Theory of, Feb., p. 34; Apr., p. 119; May, p. 20; July, p. 24, p. 46; Sept., p. 32; Nov., p. 36
Exhibition, Museum, Sept., p. 74
EXPEDITION
  Arctic, Apr., p. 88
  Eastern Mongolia, Apr., p. 78
  Polar Sea, Apr., p. 20
Fairs, Nov., p. 114
Fertility, Oct., p. 16
FISHES
  *D. fuscus*, Jan., p. 62
  Salmon, July, p. 52
Floods, Nov., p. 82
Flies, Jan., p. 56; May, p. 34
FOOD
  Apple pie, Nov., p. 114
  and Botulism, Jan., p. 12
  Boudin, Aug., p. 92
  Brunswick stew and burgoo, Sept., p. 100
  Cheddar cheese, May, p. 96
  Chopped liver, Feb., p. 102
  Clambake, June, p. 96
  and Crops, Sept., p. 26
  Giant snail, Mar., p. 103
  Gooseberry, July, p. 96
  Grain alcohol, Dec., p. 86
  Lamb, Oct., p. 94
  Mushrooms, Apr., p. 166
  Pasties, Jan., p. 100
Forestry, New England, Feb., p. 14
Fossils, Apr., p. 66; July, p. 46; Aug., p. 8
Foxes, Nov., p. 60
FUEL
  Cow and buffalo chips, Nov., p. 76
  Turf, Nov., p. 48
  Wind as, Nov., p. 70
  Wood, Feb., p. 14
Galápagos Islands, Jan., p. 62
Gamma ray, Nov., p. 108
Gardner D. Stout Hall of Asian Peoples, Sept., p. 74
GEOLOGY
  Earthquakes, Apr., p. 72; Aug., p. 70
  Lakes, Aug., p. 56
Gooseberry, July, p. 96
Great Plains, climate, June, p. 64
Hailstorms, June, p. 54
Hens, July, p. 24
Himalayas, Bhutan, Mar., p. 38
HISTORY
  of Science, Jan., p. 26; Feb., p. 34
Horses, Apr., p. 100; July, p. 24
HUMAN STRATEGY
  Punjabi villagers, Nov., p. 6
Hyenas, Feb., p. 44
Ice Age, floods, Nov., p. 82
INSECTS
  Beetles, Aug., p. 34
  Caterpillars, June, p. 42
  Flies, Jan., p. 56; May, p. 34
  Mating, Nov., p. 26
  Water bugs, Feb., p. 56
Ireland, bogs, Nov., p. 48
Japan, earthquakes, Apr., p. 72
Jupiter moon Io, Sept., p. 88
Kosher food, Feb., p. 102
Krill, Mar., p. 66
Lakes, Aug., p. 56
Loch Ness monster, Apr., p. 130
Maasai warriors, Aug., p. 42
Mackinac Island, May, p. 34
Malaria, May, p. 10
MAMMALS
  Camels, May,-p. 70
  Conservation, Apr., p. 106
  Foxes, Nov., p. 60
  Giant anteaters, Oct., p. 62
  Horses, Apr., p. 100; July, p. 24
  Hyenas, Feb., p. 44
  Man-Ape, Apr., p. 66
  Moose, Oct., p. 38
  Mule deer, Mar., p. 56
  Pocket gopher, June, p. 36
  Pygmy chimpanzees, Sept., p. 32
  Rats, Sept., p. 40
  Sheep, Mar., p. 12
  Sheep dogs, Mar., p. 12
  Shrew, Jan., p. 46
  Whales, May, p. 52
  Wolves, June, p. 58; Oct., p. 38
Man-Ape, Taungs, Apr., p. 66
MATTER OF TASTE
  Boudin, Aug., p. 92
  Brunswick stew and burgoo, Sept., p. 100
  Cheddar cheese, May, p. 96
  Clambake, June, p. 96
  County fairs, Nov., p. 114
  Giant snail, Mar., p. 103
  Gooseberry, July, p. 96
  Grain alcohol, Dec., p. 86
  Kosher food, Feb., p. 102
  Mushrooms, Apr., p. 166
  Pasties, Jan., p. 100
  Sheep, Oct., p. 94
Moas, Oct., p. 28
Moose, Oct., p. 38

Mule deer, Mar., p. 56
Museum, Hayden Planeterium, Apr., p. 31
Mushrooms, Apr., p. 166
**NATURALIST AT LARGE**
  Insects, mating, Nov., p. 26
  Malaria, May, p. 10
Nature, human evolution, Sept., p. 16
New England wood, Feb., p. 14
New York City, natural history of, Apr., p. 94
New Zealand, extinct birds, Oct., p. 28
**NUTRITION**
  and Cancer, Nov., p. 96
  Diet, July, p. 14
Opium, Oct., p. 52
Orion nebula, May, p. 80
**PAKISTAN**
  Punjabi village, Nov., p. 6
  Wind energy, Nov., p. 70
**PALEONTOLOGY**
  Piltdown skull, Aug., p. 8,
  Taung skull, Apr., p. 66
Parasites, May, p. 30
Pasties, Jan., p. 100
Pesticides, May, p. 34
Photographic competition, July, p. 30
Photographs, *Voyager*, May, p. 62
Photography, American Indian, Oct., p. 68
Piltdown skull, Aug., p. 8
Planets, Apr., p. 50
Plant cloning, Mar., p. 88
Pocket gopher, June, p. 36
Polar Sea, Apr., p. 20
Population, Sept., p. 26
Postscripts, Jan., p. 6; Feb., p. 8; Mar., p. 4; May, p. 6; June, p. 6; July, p. 12; Sept., p. 10
Pygmy chimpanzees, Sept., p. 32
Quasars, Feb., p. 78
Rats, Sept., p. 40
**RECIPE**
  Abalone, Mar., p. 103
  Apple pie, Nov., p. 114
  Boudin, Aug., p. 92
  Brunswick stew and burgoo, Sept., p. 100
  Chopped liver, Feb., p. 102
  Clambake, June, p. 96
  Fish and cheese, May, p. 96
  Gooseberry, July, p. 96
  Lamb, Oct., p. 94
  Mint julep, Dec., p. 86
  Mushrooms, Apr., p. 166
  Pasties, Jan., p. 110
**REPTILES**
  River turtles, May, p. 42
  Snakes, Feb., p. 64; Mar., p. 48
Rivers, July, p. 52
**RODENTS**
  Pocket gopher, June, p. 36
  Rats, Sept., p. 40
Salmon, July, p. 52
Samoa, children of, Apr., p. 103
Satellites, HEAD-1 and HEAD-2, Mar., p. 78
Science, multiple discoveries, Jan., p. 26
Sex ratio, male and female, Mar., p. 32
Sheep, Mar., p. 12
Sheep dogs, Mar., p. 12
Sign language, June, p. 10
Sky Reporter *see* Astronomy
Snakes, Feb., p. 64; Mar., p. 48
South Pole, polar region survey, Apr., p. 114
Spider, Jan., p. 56
Spiral galaxies, Aug., p. 80
Star SS433, Jan., p. 86
Starlings, European, Apr., p. 60
Supernova, Oct., p. 76
Survival of species, whales, May, p. 52
Swastika, Jan., p. 68
Tarantula, Mar., p. 48
Taung skull, Apr., p. 66
Telescope, July, p. 86
Teratology, Oct., p. 6
**THIS VIEW OF LIFE**
  Asteroid, June, p. 26
  Down's syndrome, Apr., p. 142
  Evolution, Feb., p. 34; May, p. 20; July, p. 24
  Nature, man's place in, Sept., p. 16
  Randomness, Nov., p. 36
  Science, immigration, Dec., p. 6; multiple discoveries, Jan., p. 26
  Scientific fraud, Aug., p. 8
  Sex ratio, Mar., p. 32
  Teratology, Oct., p. 6
**TOURIST AS PILGRIM**
  Holy Land, Jerusalem, Dec., p. 20
Toxin, botulism, Jan., p. 12
Trilobites, July, p. 46
Turtles, May, p. 42
USA, the plains, Nov., p. 76
USSR, wolf management, June, p. 58
*Voyager* spacecraft, May, p. 62
Water bugs, Feb., p. 56
**WEATHER**
  Climate, Great Plains, June, p. 64
  Hailstorms, June, p. 54
  Wind, Nov., p. 70
**WEB OF HUNGER**
  Nutrition, Dec., p. 6
  Population, Sept., p. 26
Whales, May, p. 52
Wind energy, Nov., p. 70
Wolves, June, p. 58; Oct., p. 38
Wood, firewood, New England, Feb., p. 14
Worm-Asthma, hypothesis, June, p. 20
**BOOKS IN REVIEW**
  *Bird Student*, July, p. 82
  *Birds of Paradise and Bower Birds, The*, Jan., p. 94
  *Carnivorous Plants*, Sept., p. 78

SETTLE FOR MORE

The Volkswagen Dasher isn't a down-sized something else. It wasn't wrenched into shape overnight.

It's exactly the size we had in mind, and so we've had plenty of time to make it more of a car instead of less.

For example, you have more than one choice: the 2-door hatchback, the 4-door hatchback or what we feel is the world's most fascinating station wagon.

Whichever you choose, you also get to choose either the fuel-injected gasoline engine or the optional diesel engine.

The Dasher Diesels deliver an EPA estimated 36 mpg and an extraordinary 49 mpg highway estimate. And the gasoline engine is no slouch, either, with 23 estimated mpg, 35 mpg highway estimate. Use "estimated mpg" for comparisons. Mpg varies with speed, trip length, and weather. Actual highway mpg will probably be less.

Don't go away. There's more performance than you thought: a gasoline Dasher Sedan will propel you from 0 to 50 mph in only 8.1 seconds*, quicker than a few "sportscars."

More room than you thought: the Dasher wagon holds 31 cubic feet of anything. Need still more? In 30 seconds, the rear seats fold down and you have 51.6 cubic feet.

More luxury than you thought: the carpeting in every Dasher is really plush and really everywhere. The AM/FM stereo radio is standard. So is the electric rear window defogger. The steel-belted radials. The quartz clock.

There's nothing cheap about the Dasher, including the price. But the fit and finish are equal to just about any car made.

The only thing you give up are some old-fashioned ideas about what a car ought to be.

*Dasher Diesel Sedan 0-50 mph in 13.0 sec.

# Authors

While a graduate student at the University of Arizona, **Stan L. Lindstedt** became intrigued with desert shrews because they "seem so unfit for desert survival." "Unfortunately," he recounts, "these tiny insectivores are difficult to observe. After a year and a half I had not captured *any*. Finally, with a little luck, and a good deal of persistence, I found a method for capturing them—overturning dead agave plants." Lindstedt's work on the survival of desert shrews took place in the Sonoran Desert of Arizona between 1974 and 1977. Currently an International Fellow of the Swiss National Science Foundation, stationed at the Anatomy Institute of the University of Berne, Lindstedt is again studying shrews, this time the Etruskian shrew, the world's smallest mammal. Its weight, two grams, is less than that of a dime.

Coauthor **James H. Jones** is a first-year veterinary student at Colorado State University, where he is studying aerodynamic valving of air flow in avian lungs. He has done fieldwork on bobcat density and prey selection in the central Arizona desert. On tap is research on the respiratory responses to heat stress in ostriches, which he plans to do this summer at the University of Cape Town. His involvement with desert shrews began in a graduate school course in environmental physiology at the University of Arizona in which Lindstedt was the teaching assistant. "My interest in the shrews stemmed from the subject and from Bud Lindstedt's research," Jones recalls. As a footnote, he adds, "My Ph.D. work at Duke was under the professor who had been the major professor to Lindstedt's major professor. I stayed 'in the family,' so to speak."

The web forms of spiders have a special fascination for **William G. Eberhard**. An arachnologist with a research background in behavioral biology, he has spent considerable time in the tropics studying spiders and their webs, and the insects that make adaptive use of the webs. Eberhard, who received his Ph.D. from Harvard, was once an associate professor of biology at the Universidad del Valle, Colombia. He is now on the staff of the Smithsonian Tropical Research Institute in Panama and the Escuela de Biología of the Universidad de Costa Rica.

"We were haunted by Darwin; his ghost was always around," says **John K. Stevens** about his six-week stay in the Galápagos Islands with his wife and coauthor, **Katharine E. Parsons**. They first learned of the fish they studied there while honeymooning in Maine six years ago. Born and educated in the United States, Stevens is a neurobiologist who has recently taken up a new post as associate professor of physiology at the Playfair Neuroscience Laboratory, a neurological "think tank" at the University of Toronto in Canada. His current specialty is the study of microcircuits in cats' eyes.

Parsons was a student of her husband-to-be in a college biology course. She works as a free-lance writer of health and science articles and has spent about ten years doing nature photography.

# CAN YOU AFFORD TO SUPPORT YOUR READING HABIT?

**At today's bookstore prices, who can? QPB has the answer: great books by great writers in full-size, softcover editions that are identical in page size, type size and number of pages to most hardcovers — and cost up to 65% less. Great books, great writers, great savings. Now you can afford to own the books you want to read.**

## Let's try each other for 6 months.

**Quality Paperback Book Club, Inc., Middletown, Pa. 17057.** Please enroll me in QPB and send the 3 choices I've listed below. Bill me $3, plus shipping and handling charges. I understand that I am not required to buy another book. You will send me *QPB Review* (if my account is in good standing) for 6 months. If I have not bought and paid for at least 1 book in every six-month period, you may cancel my membership. A shipping and handling charge is added to each shipment. QB113-1

**Indicate by number the 3 books or sets you want** ☐ ☐ ☐

Name______________________ 9-16

(Please print clearly)

Address______________________Apt.______

City______________State__________Zip______

**How membership works.** 1. You receive **QPB Review** 15 times each year (about every 3½ weeks). Each issue reviews a *new* Main Selection, plus scores of Alternates. All Main Selections with established publisher's list prices are offered at at least 20% discount off that list price.

2. If you want the **Main Selection** do nothing. It will be shipped to you automatically. If you want one or more Alternate books—or no book at all—indicate your decision on the reply form always enclosed and return it by the date specified.

3. **Bonus books for Bonus Points.** For each book or set you take (except the first 3 you get for $1 each), you earn Bonus Points which entitle you to choose any of the books we offer; you pay only shipping and handling charges.

4. **Return privilege.** If *QPB Review* is delayed and you receive the Main Selection without having had 10 days to notify us, you may return it for credit at our expense.

5. **Cancellations.** You may cancel membership at any time by notifying QPB. We may cancel your membership if you elect not to buy and pay for at least one book in every six-month period.

**596. The Solar Age Resource Book** Editors of Solar Age Magazine **QPB: $7.95**

**561. Of Wolves And Men.** Barry Holstun Lopez. Hardcover: $14.95 **QPB: $6.50**

**316. BBC TV Shakespeare Set** *Henry VIII, Romeo and Juliet, Richard II, As You Like It, Julius Caesar, Measure for Measure.* (6 Vols.) **QPB: $15.95**

**108. Anatomy Illustrated** Emily Blair Chewning Designed by Dana Levy **QPB: $5.95**

## Join now. Pick any 3 books or sets for $1 each—with no obligation to buy another book.

**392. A History Of Films** John L. Fell. **QPB: $9.95**

**565. Utopia:** An Illustrated History. Ian Todd and Michael Wheeler **QPB: $6.95**

"The strikingly different uses of the swastika in the Third Reich and in India lead inevitably to speculation about its original meaning," says **Stanley A. Freed**, who with coauthor **Ruth S. Freed** has studied urban influences and modernization in a village in northern India. The Freeds first did fieldwork in the village from 1957 to 1959 and recently returned from a follow-up trip on which they noted the changes that have occurred during the last twenty years. Both authors are Ph.D.s in anthropology from the University of California at Berkeley and have done research among several North American Indian groups. Stanley A. Freed is curator of anthropology at the American Museum of Natural History. Ruth S. Freed, professor of anthropology at Seton Hall University, New Jersey, is a research associate in the Museum's Department of Anthropology.

As a college student, California-born **Henry T. Lewis** began spending the first of eleven summers fighting forest fires as a park ranger with the National Park Service. In an attempt to understand why California Indians had traditionally set fires in grasslands, brush, and forests, he learned that their strategy was similar to what fire ecologists currently advocate for the management of wildland areas. This discovery led to his monograph on *Patterns of Indian Burning in California* and to his more recent research and a film on the Indian uses of fire in northern Alberta. Now a Canadian citizen and chairman of the Department of Anthropology at the University of Alberta in Edmonton, Lewis is making a comparative study of aboriginal uses of fire in the tropical savanna region of northern Australia.

# Fill out this coupon and save the children

Complete this simple questionnaire, and befriend a needy child through Save the Children. For only fifty-two cents a day, your money, combined with that of other sponsors, can breathe new life into an impoverished village…help hardworking people in their fight for dignity…turn despair into hope for a child who has known only disaster. Fifty-two cents may not buy much where you live. But for the poorest of the poor where the need is so desperate, it can work miracles. NH1/80

My Name Is ____________________ (please print)

Address ____________________

City ______________ State ______________ Zip ______________

## Tell us how you want to help, by answering these questions:

### 1. What kind of child would you like to help?

☐ Boy ☐ Girl ☐ No preference

### 2. What geographical area are you interested in?

Urgent need exists in all the areas listed below, especially overseas. If you have a strong preference for a particular location, check the area of your choice. If not, won't you please let us assign a child where the need is greatest?

☐ **Certainly. Choose a child for me in an area of greatest need.**

**I strongly prefer:**

☐ Africa
☐ Bangladesh
☐ Chicano (U.S.)
☐ Colombia
☐ Dominican Republic
☐ Honduras
☐ Indian (U.S.)
☐ Indonesia
☐ Inner Cities (U.S.)
☐ Israel
☐ Korea
☐ Lebanon
☐ Mediterranean
☐ Mexico
☐ Southern States (U.S.)
☐ Sri Lanka (Ceylon)

### 3. Would you like a picture of your sponsored child?

Shortly after we select a child for you, we can send you a photograph and brief personal history, if you desire.

☐ Yes ☐ No

### 4. Would you like to exchange correspondence?

If desired, correspondence can build a meaningful one-to-one relationship and provide a unique educational experience for the sponsored child. In areas where illiteracy is high, a village representative will keep you informed of the progress your child is making. Translations, where necessary, are supplied by Save the Children.

☐ Yes ☐ No

### 5. Would you like information about the child's community?

Several times a year you can receive detailed reports on the activities and projects being undertaken in the community to benefit your sponsored child. These community reports show how your money is being used most effectively for permanent improvements to the child's environment—for health care, education, food production, nutrition, and community training. Would you like to receive such information?

☐ Yes ☐ No

### 6. How do you wish to send your sponsorship contribution?

Enclosed is my check for $________.

☐ Monthly, $16 ☐ Semi-annually, $96
☐ Quarterly, $48 ☐ Annually, $192

### 7. Do you wish verification of Save the Children credentials?

Save the Children is indeed proud of the handling of its funds. Based on last year's audit, an exceptionally large percentage (80.3%) of each dollar spent was used for program services and direct aid to children and their communities. Due to volunteered labor and materials, your donation provides your sponsored child with benefits worth many times your total gift. Would you like to receive an informative Annual Report (including a summary financial statement)?

☐ Yes ☐ No

*(A complete audit statement is available upon request.)*

### 8. Would you rather make a contribution than become a sponsor of an individual child at this time?

☐ Yes, enclosed is my contribution of $________.

☐ Check here for general information about our unique programs for aiding impoverished children.

## Tahoe's Decline

Last fall, Charles Goldman climbed into a seventeen-foot submarine and dove 1,000 feet beneath the surface of Lake Tahoe. It was his first chance to see the depths of a lake he has studied for twenty years. And what he saw in the course of several dives confirmed the assessment that he and the Tahoe Research Group made in "Tahoe's Troubled Waters" (*Natural History*, January 1975)—"Tahoe is changing for the worse each year."

One of the things Goldman saw was attached algae growing as far down as 600 feet. Tahoe is naturally nutrient poor and would not be expected to have much algal growth. Nonetheless, it has been increasing in fertility over the years because of construction and development around the lake. These disturbances add to the burden of sediment (and nutrients) that streams and spring runoff carry into the lake. Goldman also saw vast areas of lake bottom covered with fine sediment that looked "like a blanket of ooze."

Most important, according to Goldman, was his discovery of large numbers of pregnant mysis shrimp near the bottom of the lake. After their introduction as fish food about six years ago, mysis devastated two native forms of zooplankton, *Daphnia* and *Bosmina*. Recent surface counts have shown the shrimp population to be leveling off, but since pregnant mysis are staying near bottom and not migrating to the surface at night as they generally do, those counts are probably low.

Goldman's underwater exploration, which was financed by a California newspaper, the *San Jose Mercury News*, was not without its pleasures. He got a "completely new perspective on the lake" and was particularly surprised by the "incredible diversity of the underwater habitat," which ranged

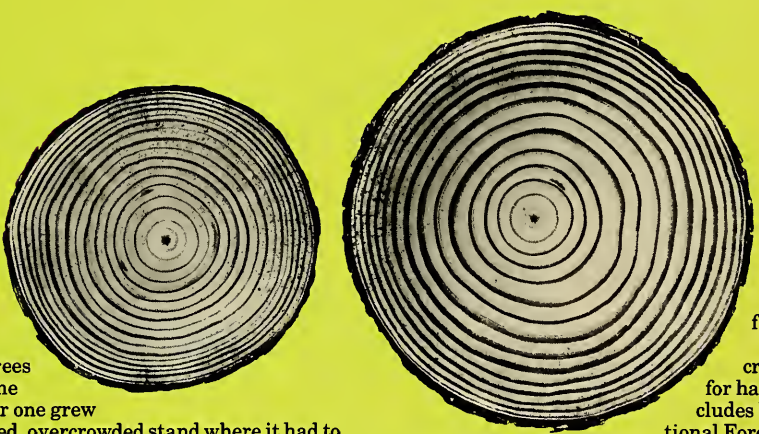
UPI

A report on the great American forest.

# Look what happens when Mother Nature gets a little help.



These log slices dramatically show the value of modern, scientific forest management. Both (shown 36% of actual size) are from trees of about the same age. The smaller one grew in an unmanaged, overcrowded stand where it had to compete for sunlight and moisture. The other is from a grove that was thinned to give the best trees room to thrive.

This is just one of many ways forest management can help meet a predicted doubling of domestic demand for wood and paper products in the next 50 years.

The forest industry has learned how to help Mother Nature grow more trees, faster, by applying scientific forest management techniques: encouraging natural regrowth, planting superior seeds and seedlings, fertilizing, protecting against disease and insects, thinning, watching carefully until time to harvest — then starting the cycle again.

## Demand keeps rising.

Forest management like this is vital because every year Americans need more homes, more paper products, more packaging and containers, more fuelwood, more of the thousands of other essential products that only the forest can provide.

So far, the country's commercial forest has been able to keep up with demand. (*Commercial forest,* as defined by the U.S. Forest Service, is *all* forestland—whether owned by individuals, government or the industry—that is capable of, and potentially available for, growing repeated crops of trees for harvest. It includes land in National Forests but not in National Parks or Wilderness areas.)

But trees aren't grown equally fast by all commercial forest owners. Though industry has made striking advances on its lands, productivity is lower on privately owned lands and seriously lagging in National Forests.

## Productivity not up to potential.

Overall, the U.S. Forest Service estimates average productivity of all commercial forestland is only 61 percent of potential. And at the same time, actual acreage in commercial forests keeps shrinking, as land is withdrawn for homes, highways and other needs of an expanding population.

So we as a nation still have a long way to go if our wood and paper products are not to become scarce and expensive.

If you'd like to be better informed on how important it is to keep America's forests productive, write American Forest Institute, P.O. Box 873, Springfield, VA 22150 for a free booklet, "The Great American Forest."

The great American forest. Trees for tomorrow. And tomorrow. And all the tomorrows after that.

**Trees. America's renewable resource.**

from ooze-covered bottom to grassy hills to the sheer cliffs of underwater canyons.

## Good News, Bad News

Mark Newton and Russell Smith saw a bleak future ahead for the California mountain king snake when they wrote "The Snake That Lost Its Habitat" (*Natural History*, June/July 1975). An "ice age relict" that has little appropriate habitat left in the state, the snake occupies a particularly precarious niche in the Santa Monica Mountains near Los Angeles. There, it lives only in the canyons, a habitat that is also popular with developers.

The good news is that in 1978 Congress passed the National Parks and Recreation Act, creating, among other things, the Santa Monica Mountains National Recreation Area, a 150,000-acre chunk of the mountain range within which the National Park Service is to buy undeveloped land. A land acquisition plan was due to Congress at the beginning of 1980, and in fiscal 1980 the Park Service is getting its first acquisition funds.

The problem is in turning the legislative mandate into an actual park. The Park Service has been authorized to spend $155 million over five years to buy land; of that, $35 million is for 1980. The White House tried to trim this year's funds to $13 million, but Congress restored the balance. Even so, land in the Santa Monicas goes for astronomical prices, with some of the more luxurious homes costing $1 million or more. And as might be expected, the Park Service will not always be dealing with willing sellers. Developers are opposed to the park and have threatened to force the Park Service into lengthy law suits.

Finally, the Park Service is not the only government body concerned with the Santa Monicas. The city of Los Angeles and several smaller communities, each with their attendant agencies, the state Coastal Commission, and Los Angeles and Ventura counties all have some stake in the mountain range.

Even with the money and the law behind it, the Park Service's work has just begun.

## The War on Evolution

In the 1970s, wrote Norman Newell in "Evolution Under Attack" (*Natural History*, April 1974), believers in the biblical account of creation renewed their crusade against the teaching of evolutionary theory in the public schools. Now they have carried the fray from classroom to museum, challenging an exhibit on evolution in the Smithsonian Institution's new National Museum of Natural History.

Modern creationists are biblical fundamentalists, but frequently go forth into the courts under the banner of science, not religion. They claim that the notion that God created the world and all basic kinds of living things in the biblical six days is supported by the scientific evidence. On the other hand, creationists also claim that the theory of evolution is not science at all, but disguised theology.

In the court challenge to the federally financed Smithsonian exhibition—"Dynamics of Evolution"—Dale Crowley, director of the National Foundation for Fairness in Education in Washington, D.C., said the Congress was, in effect, financing religion. He charged that by presenting only the theory of evolution without information on other theories of creation, the Smithsonian was using public money to establish a "religion of secular humanism" and therefore violating First Amendment provisions for separation of church and state.

In the suit filed in federal district court in Washington, Crowley said that he and his coreligionists were forced either to violate their beliefs by visiting the evolution exhibit or to give up their right of access to public property. In addition, he said, the Smithsonian was out of bounds in giving any interpretation to the animals and other items in the exhibit, since its congressional mandate was only to display objects, not to interpret them.

Judge Barrington D. Parker was not impressed with Crowley's arguments and dismissed his suit, saying that the Smithsonian had not only the right but the mandate to diffuse scientific knowledge and that the theory of evolution, as presented by the museum, was indeed science and not religion. As to whether the offensiveness of the exhibit infringed on Crowley's rights, the judge quoted the Supreme Court decision in a similar case: "The state has no legitimate interest in protecting any or all religions from views distasteful to them."

The exhibit opened last spring but the decision was appealed, and until the legal struggles are over, no one at the Smithsonian cares to comment on them.

OF WOLVES AND MEN

Explore and enjoy
the wonders of nature in the pages
of the finest nature books being published today —
all available to you at substantial savings
when you join Nature Book Club

**Take any 4 for only $2.95**

**to start your Nature Book Club membership** (up to $70.40 worth of books)

As a Nature Book Club member you'll be offered books on all aspects of nature: birds, animals, fish, trees, wildflowers, wilderness, natural history and science and much more. These books will include field guides to birds, wildflowers, mushrooms, rocks and minerals, etc. And books on our national parks, travel guides to wilderness areas, books on hiking, backpacking and camping, self-sufficiency, outdoor photography . . . You will be offered (often at half price or less) big, luxurious full-color nature books that sell for $35 or more in stores. And books on mountains, deserts, oceans . . . dramatic geographic areas . . . spectacular species like the big cats. You will be offered many wonderful "reading" books — on ecology, biology, geology, natural history . . . all kinds of nature subjects. **As a Nature Book Club member you get all books at up to 50% off the publisher's price** (and sometimes even more). Yet in virtually every case Club books are identical to publishers' editions — same jacket, binding, cover, paper, printing —same everything except price.

**How The Club Works**

First, just pick any four of the books listed here (up to $70.40 worth of books). Indicate your choices on the attached card and mail. Send no money now. We'll bill you later for only $2.95 plus delivery and handling.

Then, about every four weeks (14 times a year), you'll receive a Club bulletin describing the coming main selection and alternate books also available, all at Club discounts. If you want the main selection only, do nothing. It will be sent automatically. If you don't want the main selection, or want alternate books, or no books, please make sure to indicate your wishes on the Instruction Form and return it to us (no envelope required) by the date shown. Club mailings are carefully scheduled to assure you of at least 10 days in which to do this. But in the unlikely event that you don't have 10 days, and you receive an unwanted selection, you may return it at our expense.

After receiving your joining shipment, your only obligation is to buy two more regular selections or alternates in the next year. After that, membership may be cancelled at any time, by either you or the Club.

# Deadly Botulism

*Lethal and incurable, this centuries-old disease is now thought to be the cause of some cases of infant crib death*

### by Lance L. Simpson

Botulism is to modern medicine what Billy the Kid was to the Old West. It is an ornery and untamed disease known widely for its killing ways. Botulism has earned this notorious distinction for two reasons. First, it is caused by botulinum toxin, a substance that is nature's most deadly poison. Second, it is not curable. Patients struck by the disease can survive only if their bodies can withstand the toxin's assault upon their nervous systems.

Botulism is most commonly encountered as a form of food poisoning. Both history and legend suggest that this type of food poisoning has been known for centuries. During the past few years, however, medical investigators have discovered a new and unsettling aspect of botulism that, sadly enough, can only increase our fear of this disease. To understand why, we must first understand something about the toxin and about food poisoning.

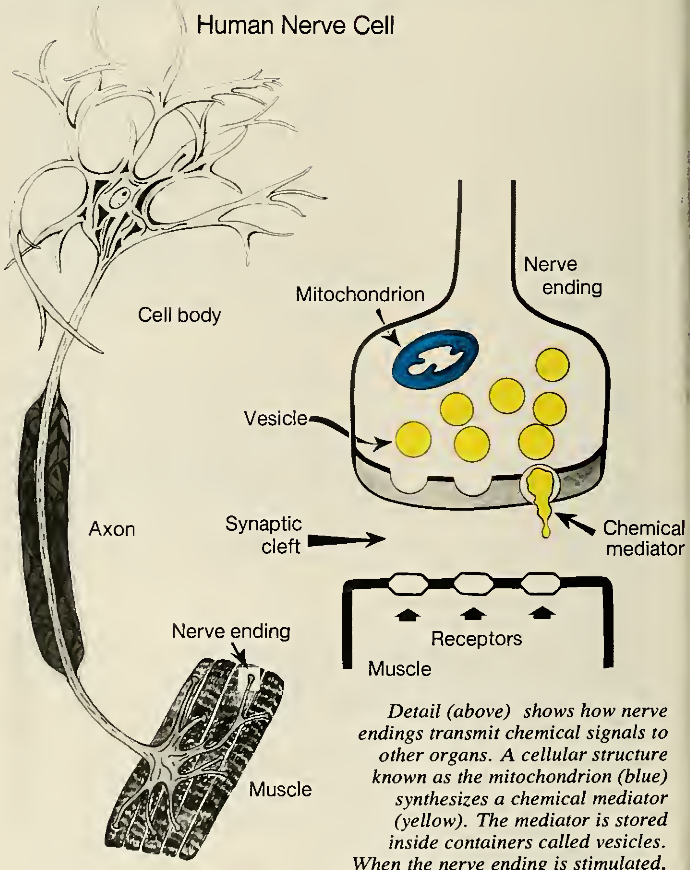
Botulinum toxin is produced by the bacterium *Clostridium botulinum*, an organism closely related to *C. tetani*, the bacterium that produces tetanus toxin. Were it not for the existence of botulinum toxin, tetanus toxin would be regarded as the most deadly poison.

Botulinum toxin is synthesized in at least eight immunologically distinct types. Generally speaking, individual strains of *C. botulinum* synthesize only one type of toxin. Although they differ in their immunogenicity, the various toxins all have a similar mechanism of action in poisoning the nervous system. Epidemiological studies have shown that human outbreaks of botulism are associated with four types of toxins. Of these, the type known as A toxin is the most lethal and the one that has been most carefully studied.

For type A toxin to cause an outbreak of food poisoning, an unbroken chain of events must occur. First, and most obvious, a potential food must be contaminated with *C. botulinum*. Next, the food must be packaged in a way that will permit the bacteria to grow and multiply, and in so doing produce the deadly toxin. Clostridia are anaerobic organisms; that is, they can live in the absence of oxygen and can grow inside most containers used by commercial food processors. To prevent the growth of clostridia and the production of toxin, food processors use various techniques: the most common is heating foods to high temperatures. This retards bacterial growth and completely destroys any toxin that may have formed. In addition, most processed foods are cooked before they are eaten, and this step inactivates the toxin molecule, which is unstable at high temperatures.

An outbreak of botulism is possible only if a food is contaminated with

*Please turn to page 18*



*Detail (above) shows how nerve endings transmit chemical signals to other organs. A cellular structure known as the mitochondrion (blue) synthesizes a chemical mediator (yellow). The mediator is stored inside containers called vesicles. When the nerve ending is stimulated, the vesicles release the mediator, which diffuses across the synaptic cleft and triggers an impulse in the muscle.*

# The 100 Greatest Books Ever Written

***The World's Greatest Works of Literature · Beautifully Illustrated***
***Bound in Genuine Leather · Decorated With Real Gold***

For generations, men and women of culture have collected leather-bound volumes of the world's great classics — for their own enjoyment and to hand down to their heirs. Now, with this invitation, you can affordably acquire "The 100 Greatest Books Ever Written" in one of the most luxurious leather-bound editions ever published.

It is not difficult to list the world's greatest books. The titles and authors leap quickly to mind. And for good reason. The books that have been recognized as great, generation after generation, are part of the world we live in. They have shaped our lives, our language, our values, our outlook.

These books include novels like Melville's *Moby Dick*, Dickens' *A Tale of Two Cities*, Hawthorne's *Scarlet Letter*, Brontë's *Wuthering Heights*. They include serious — yet highly readable — works of thought like Plato's *Republic* . . . heroic epics like Homer's *Iliad* . . . sharp-witted satire like Swift's *Gulliver's Travels* . . . brilliant poetry like Whitman's *Leaves of Grass*.

On everyone's list would be the great works of Shakespeare, Chaucer, Dante, Darwin, and Twain. These are books you want on your bookshelf. Books you want your children and their children to read. And now you can have them — the ultimate private library.

*(Continued on next page)*

# The 100 Greatest Books Ever Written

*(continued from previous page)*

### The Volumes Themselves are Works of Art

Your pride in this collection will be twofold — arising both from the significance and stature of each literary masterpiece . . . and from the sheer beauty of each volume.

Every volume in this unique private library will exemplify the ultimate in the art of printing, binding, and illustration. The paper on which these books are printed will be specially milled — to endure for generations. Each book will be bound in leather, inlaid with a 22 karat gold design which sets it apart from all other volumes in the collection.

### Genuine Leather Bindings

Today it is rare to find books bound in genuine leather. The cost of such bindings and the time required to create them has made the crafting of such bindings an almost vanishing art.

**But each book in this collection will be bound in genuine leather!** The leathers used will be only the finest, and many different types of leathers will be used — calfskin, cowhide, suede, sheepskin — to give even greater distinction to the total collection.

As with every detail of these books, luxury in binding will be the rule rather than the exception. Each volume will have the beautiful lustre, wonderful feel, and distinctively rich smell that is characteristic of only *genuine* leather.

### Intricate Cover Designs and Gilt-edged Pages of Real Gold

Each luxurious leather binding will be deeply inlaid with real gold — not only on the front cover, but also on the back cover and the spine. Then, to bring out the full beauty of each cover design, every page will be gilt-edged with this precious metal.

### Elegant Finishing Touches

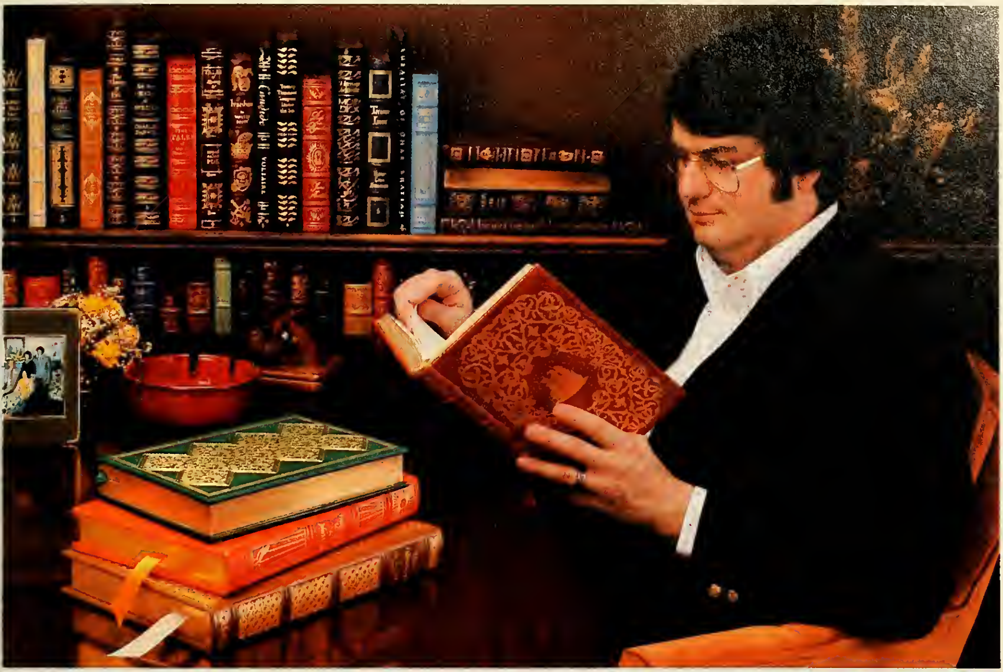
Each volume will have beautiful endsheets of rich moiré fabric and a matching ribbon page marker. Each volume will be bound with a "hubbed" spine that is characteristic of only the finest books. In every respect, this is to be a collection which rivals anything seen in the great private libraries of days gone by.

### Exciting Diversity

The hallmark of a distinctive library is diversity. Therefore, the volumes in the collection will vary in size, in the leathers used, in the gold designs on each binding, and in the illustrations. Yet the collection as a whole will exhibit an unmistakable harmony, because the volumes will be of consistent quality throughout.

### A Truly Personal Library.

When you acquire this edition of "The



100 Greatest Books Ever Written" you are building a personal library that will be one of your most prized possessions. To beautifully identify each book in the edition as part of your own private collection, a personalized nameplate will accompany every volume.

### Convenient Acquisition Plan

Because of the extreme care and craftsmanship required in printing and binding, the books in the collection will be issued at the rate of one per month. It will give you great pleasure to see your collection becoming more impressive with each passing month.

Comparable books bound in genuine leather command as much as $50 to $75 per volume. However, you will be pleased to learn that the volumes in this collection will be priced at only $31.50 each for the first two full years. Future volumes will be similarly priced subject to minor periodic adjustments to reflect varying material costs.

If you desire, you may return any volume within 30 days for a full refund. Moreover, you need purchase volumes only as long as you choose to do so; you may cancel your subscription at any time.

### R.S.V.P.

To accept this invitation, you need only complete the Preferred Subscription Reservation and return it to us. This simple step is all that is necessary for you to begin building a private library of your own that is sure to be envied by all who see it.

**Connecticut residents pay $35.58 to include sales tax clostridia and if the food is packaged in a way that permits growth of anaerobes. At the same time, the packager must neglect to use techniques that retard bacterial production of toxin, and the consumer must fail to cook the contaminated food. The low incidence of botulism indicates that this chain of events is not likely to occur.

Nevertheless, accidents do happen. Each year there are several outbreaks of botulism. Sometimes the outbreak is confined to one family, as is usually the case when a home-canned food is implicated. More tragically, the outbreak may involve dozens of people, all of whom have consumed a commercially prepared and distributed food. In either case, the clinical outcome is the same.

To understand how botulinum toxin exerts its poisonous effects, we must take a close look at the human nervous system and its fundamental component, the individual nerve cell. Each nerve cell has three main parts—a cell body, an axon, and a nerve ending. A nerve impulse normally arises in or near the cell body and is conducted outward by the axon. The nerve ending, or terminal, is a specialized structure that transmits impulses from itself to the structure that it innervates, or is connected to, for example, another nerve, a muscle, or a gland.

Nerve endings are not electrically coupled to the organs they innervate. Therefore, a nerve action potential that is propagated down the axon into the terminal cannot electrically excite the organ to which it is connected. There are several reasons for this; the most important is that a small anatomical cleft, the synapse, separates nerve endings from the structures they innervate. The gap created by the synapse prevents nerve endings (presynaptic structures) from being electrically coupled to innervated organs (postsynaptic structures).

In humans, synaptic transmission is a chemical process. Chemical mediators, known as synaptic transmitters, are stored inside microscopic containers, or vesicles. When an action potential invades the nerve terminal, it causes these vesicles to migrate toward the nerve membrane and dump their transmitter substance into the synaptic cleft. The transmitter diffuses across the synapse and collides with receptors on the postsynaptic cell. The result of this drug–receptor collision is the initiation of a new action potential.

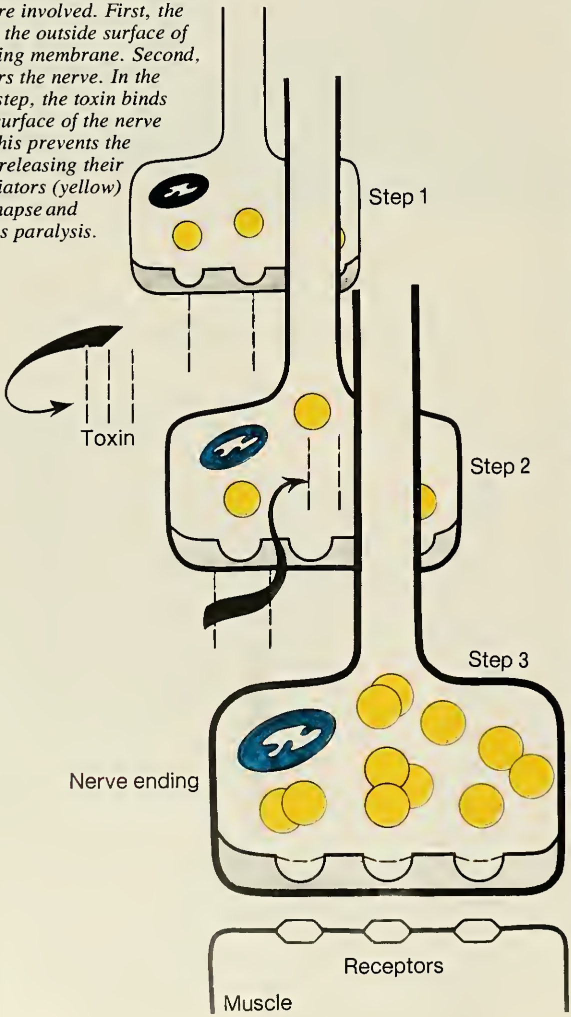
There are many different synaptic transmitters in the human body. Interestingly enough, botulinum toxin paralyzes only those synapses at which the transmitter substance is acetylcholine, a compound that has numerous effects on the human body. This specificity of toxin effect is advantageous to scientists because much is known about acetylcholine-mediated transmission.

Acetylcholine is synthesized inside the nerve ending. Two small molecules, acetate and choline, are enzymatically linked to form the transmitter. Once synthesized, acetylcholine is stored inside vesicles. When a nerve impulse flows into the nerve ending, the vesicles migrate toward the presynaptic nerve membrane, then jettison their stores of acetylcholine into the synapse. The transmitter substance diffuses across the synapse, where it promptly bumps into cell receptors. As already explained, the acetylcholine–receptor collision triggers a new impulse.

Scientists have known for many years that botulinum toxin poisons cholinergic transmission, but research is still being done to determine pre-

## Interaction between Botulism Toxin and Nerve Ending

*Three steps are involved. First, the toxin binds to the outside surface of the nerve ending membrane. Second, the toxin enters the nerve. In the crucial third step, the toxin binds to the inside surface of the nerve membrane. This prevents the vesicles from releasing their chemical mediators (yellow) across the synapse and thereby causes paralysis.*



Zena Lupjan

# He created some of the world's most passionate music.

# Yet he died whispering the name of a woman he had never met.

She was his patroness...his confessor...his "Beloved Friend" in an intimate 14-year correspondence. She was the inspiration for his most romantic works. And yet he shrank from meeting her even when she invited it.

Finally, she withdrew her support from him. Yet years later, on his deathbed, he whispered her name. In gratitude? In love? In anger? The secret died with Tchaikovsky. But the passion that Nadezhda von Meck inspired lives on in some of the most soaringly romantic melody ever penned, as you will discover in TIME-LIFE RECORDS' magnificent four-stereo-record album, *Tchaikovsky*—your introduction to the outstanding series GREAT MEN OF MUSIC.

Here is a connoisseur's choice of Tchaikovsky's creations, recorded in finest stereo sound by artists who have no peer. You'll hear Van Cliburn's rendition of the *Piano Concerto No. 1 in B Flat Minor*...Jascha Heifetz and the Chicago Symphony Orchestra (conducted by Reiner) playing the *Violin Concerto in D Major*...the *Symphony No. 6 in B Minor (Pathetique)*, performed by the Boston Symphony Orchestra, conducted by Monteux.

The boxed set on Tchaikovsky is only the beginning of GREAT MEN OF MUSIC—an unparalleled collection of the world's greatest music, performed by leading artists of our time. In future albums, you will thrill to the genius of Bach, Beethoven, Mozart, Brahms, Mahler...over 20 composers. And you'll listen with new understanding because each album is enriched with a color-filled booklet on the composer, plus illuminating notes about the music.

Start by auditioning *Tchaikovsky* for 10 days free. You'll receive four 12-inch LP stereo records (the kind that usually retail for $6.98 each) in an elegant slipcase, the background booklet complete with Listener's Guide, AND the $19.95 deluxe edition of *The Golden Encyclopedia of Music*—yours free just for purchasing *Tchaikovsky* and agreeing to audition future albums.

If after ten days you decide you'd like to own this $47.87 value, it's yours for only $19.95, plus shipping and handling. If, however, you are not completely delighted, return the album and encyclopedia and owe nothing. Send no money. Just mail the attached card. Or write TIME-LIFE RECORDS, Time & Life Bldg., Chicago, IL 60611.

**FREE BOOK!** *(with purchase of Tchaikovsky album)*

TIME LIFE RECORDS

How to buy value in art.

"Greasborough Dusk," an original lithograph by George Guest. At $130 it typifies the very remarkable value that Christie's Print Collection offers in original etchings, lithographs, linocuts, etc. Attractive landscapes and figurative works by rising young artists from around $100 to $150. And of course the works of such masters as Chagall, Miro, Moore.

Each work is an authentic original, numbered and signed by the artist. Then it is stamped with Christie's seal of authentication and delivered to your home.

Let us send you our free colour portfolio and price list. There's no better place to buy original prints. There's no better time than now.

cisely what happens. Investigators believe that the interaction between the toxin molecule and the nerve ending is complex. More precisely, they believe that at least three sequential steps are involved and that when all three have been completed, the cholinergic synapse becomes helpless and paralyzed.

In the first step, the toxin binds to the outside surface of the nerve membrane, but this binding does not alter the function of the nerve cell. In the second step—referred to as a translocation step—the toxin molecule, or some portion of it, enters the nerve. There is uncertainty about how the toxin molecule gets from the outside to the inside of the nerve, but according to one intriguing hypothesis, empty vesicles that have released their acetylcholine into the synapse may capture the toxin molecule and transport it back into the nerve cell. There are, of course, other possibilities.

The third and crucial step in the sequence is the one that produces paralysis of transmission. Most investigators believe that once inside the nerve, the toxin molecule binds to the internal surface of the nerve membrane. In so doing, it causes a change in the structure or function of the nerve membrane. As a result, vesicles can no longer meld with the nerve membrane to release their stores of acetylcholine. In effect, the toxin produces a "logjam." Although nerve impulses can still be propagated into the nerve endings, they do not cause the vesicles to discharge their acetylcholine. Instead, as time passes and the number of nerve impulses increases, the vesicles become backed up, in logjam fashion, inside the nerve terminal.

This sequence of events seems very intricate, an impression that might be true if attention were limited to botulinum toxin. But if we examine the actions of other bacterial toxins that can cause poisoning, a fascinating trend begins to emerge. Most of the truly poisonous toxins, such as cholera, diphtheria, and tetanus toxin, possess similarities to botulinum toxin. Most notably, all of these toxins bind to the outside of their target cells without producing any ill effects. Only when the various toxins move inside their target cells do they begin to cause damage.

The target cells upon which botulinum toxin acts are cholinergic nerves. Cells of this type are found in both the central nervous system (the brain, for example) and the peripheral nervous system. Patients who suffer from botulism, however, experience poisoning only of their peripheral nerves. The brain is protected by a functional and morphological shield called the blood-brain barrier. Botulinum toxin cannot penetrate this barrier, so central cholinergic nerves are spared.

The peripheral nervous system has two major divisions, the motor system and the autonomic system. The motor system governs all types of voluntary movement, such as walking, talking, and breathing. Virtually all motor nerves are cholinergic and as such are vulnerable to botulinum toxin. The victims of severe botulism will experience complete paralysis of all voluntary nerves.

The autonomic nervous system governs the function of many body organs not under voluntary control, such as the heart, the vasculature, the bowel, and the bladder. Many, but not all, autonomic nerves are cholinergic. Those that are can be poisoned by botulinum toxin. The effect of the toxin manifests itself in many ways, including erratic blood pressure and heart rate, constipation, and urinary retention.

Some organs, like the eye, have both voluntary and autonomic innervation. As a result, the function of the eye is especially impaired by botulinum toxin; symptoms include dilated pupils and blurred and double vision.

For the patient stricken with botulism, the experience can be devastating, if not fatal. The patient with severe botulism cannot move, cannot even breathe. All voluntary muscles are paralyzed. In addition, there is widespread disruption of autonomic function. Unfortunately, there is no cure for botulism. There is no form of drug treatment, and certainly no surgical procedure, that abolishes the symptoms of the disease. Instead, physicians must rely on two poor substitutes for a cure, these being supportive therapy and time.

Supportive therapy is an integral part of the practice of medicine. Loosely speaking, supportive therapy means the use of artificial methods to sustain a bodily function. For example, a botulism patient who cannot breathe or who has difficulty breathing can be maintained on artificial respiration. Likewise, the patient who cannot eat or swallow food will be fed intravenously. If the bowel or bladder is not working properly, artificial techniques can be used to void the body of its excreta. In short, every effort is made to

sustain those bodily functions that have fallen prey to botulinum toxin.

The second factor is time. If there is any ray of hope for the botulism victim, it is that the effects of the toxin are reversible. After many days or, in severe cases, many months, toxin-induced paralysis diminishes and then disappears.There is as yet no clear explanation for why the paralytic symptoms disappear, but there is a widely held assumption. As time passes, the nervous system may synthesize replacement parts for those that were attacked by the toxin. Therefore, the goal of the physician is to provide whatever supportive therapy may be needed so that the nervous system will have time to mend itself.

In its best-known guise—as a form of food poisoning—botulism is a disease worthy of dread. It is hard to imagine learning anything that could make the disease appear even worse than it already is. But something new and unpleasant has been learned.

Strictly speaking, foodborne botulism is not an infection; it is a form of intoxication. Ingestion of the bacteria does not cause sickness. By contrast, ingestion of the toxin can be fatal. These matters prompt us to ask a logical question: If someone accidentally ingests some clostridia, will the bacteria synthesize toxin inside the victim's body, thus causing paralysis? This question and the answer to it have led to a chilling new discovery.

Ordinarily, *Clostridium botulinum* cannot grow and multiply inside the human body, so its toxin cannot be synthesized and released. In part, the organism does not grow well because it is an anaerobe, and the healthy human body is not an ideal growth medium for anaerobes. However, there is a more important factor to be considered. Within the human body, and the gut in particular, various types of bacteria compete with one another for their own biological niche. *C. botulinum* is a rather weak competitor and as such is not able to secure a niche; that is, it cannot compete effectively when the human gut has its normal quota of bacteria. If the normal quota is not present, however, matters can be quite different.

There is a time during the human life cycle when few bacteria are present in the gut, when bacterial competition has not reached a furious pitch, and when *C. botulinum* can grow and produce its deadly toxin. Shortly after birth, the human infant's gut is virtually bacteria free. If at this vulnerable time of life, *C. botulinum* bacteria enter and colonize the gut, the outcome can be a tragic case of botulism.

Within the recent past, the first cases of infant botulism have been discovered. Futhermore, the incidence, or at least the ascertainment, of the disease is increasing. Some physicians fear that the incidence of infant botulism may exceed that of the better-known foodborne botulism. They also fear that many previous cases of infant botulism may have been wrongly diagnosed as other serious problems, such as the sudden infant death syndrome known as "crib death."

As its name implies, sudden infant death syndrome occurs rapidly and for no apparent reason. For years, scientists have sought an explanation for this mysterious form of death. With the discovery of infant botulism, the hypothesis arose that some cases of crib death might have been caused by botulinum toxin. This hypothesis is now being carefully examined by many pathologists.

At the moment, medical investigators and public health officials are working vigorously to determine the true incidence of infant botulism. They are also searching for ways to prevent the disease from occurring and ways to treat it when it does occur. Clearly, these concerns are equally germane to foodborne botulism. Whether botulism originates from poisoning or as an infant infection, preventive and curative measures are desperately needed.

The reader will probably be surprised to learn that preventive measures are, at least potentially, already available. There does exist a botulinum toxoid that confers immunity to botulism, but it has not been, and may never be, marketed. The pharmaceutical industry believes that the general public is not strongly motivated to seek immunization against botulism. According to this belief, it would not be cost-effective to develop and market the toxoid because too few people would want to be immunized.

Current research is focused almost exclusively on developing a cure. But even the most optimistic scientist would concede that that is not on the near horizon. For the time being, botulism remains a tragic and often fatal disease for which there is no cure.

*Enter the world of Questers nature tours.*

When you travel with Questers, you have the advantage of our knowledge of the travel world. And our experience of the natural world. We are travel professionals. And our only tour program is Worldwide Nature Tours.

Under the leadership of an accompanying naturalist, we search out the plants and animals, birds and flowers... rain forests, mountains, and tundra... seashores, lakes, and swamps of the regions we explore. At the same time, we include the more usual attractions in touring—the cities, archaeological sites, and people.

The current Directory of Worldwide Nature Tours describes 29 tours varying from 9 to 36 days and going to virtually every part of the world. Included are The Amazon, Peru, Patagonia, Galapagos, Hawaii, Alaska, Death Valley, Everglades, Ladakh, Sri Lanka, Iceland, Scotland, Greece, Australia, and New Zealand. Tour parties are small, the pace leisurely, and itineraries unusual.

*Call or write Questers or see your Travel Agent today for your free copy of the Directory of Worldwide Nature Tours.*

# Wallace's Fatal Flaw

*"I hope," wrote Darwin, "you have not murdered . . . your own and my child"*

In the south transept of Chartres cathedral, the most stunning of all medieval windows depicts the four evangelists as dwarfs sitting upon the shoulders of four Old Testament prophets—Isaiah, Jeremiah, Ezekiel, and Daniel. When I first saw this window as a cocky undergraduate in 1961, I immediately thought of Newton's famous aphorism—"If I have seen further it is by standing on the shoulders of Giants"—and imagined that I had made a major discovery in unearthing his lack of originality.

Years later, and properly humbled for many reasons, I learned that Robert K. Merton, the celebrated sociologist of science from Columbia University, had devoted an entire book to pre-Newtonian usages of the metaphor (*On the Shoulders of Giants*, Harcourt, Brace and World, 1965). In fact, Merton traces it back to Bernard of Chartres in 1126 and cites several scholars who believe that the windows of the great south transept, installed after Bernard's death, represent an explicit attempt to capture his metaphor in glass.

Although Merton wisely constructs his book as a delightful romp through the intellectual life of medieval and Renaissance Europe, he does have a serious point to make. Merton has devoted much of his work to the study of multiple discoveries in science. He has shown that almost all major ideas arise many times, usually independently and virtually at the same time. Thus, great scientists are embedded in their cultures, not uniquely divorced from them. Most great ideas are "in the air," and several scholars simultaneously wave their nets.

One of the most famous of Merton's "multiples" resides in my own field of evolutionary biology. Charles Darwin, to recount the famous tale briefly, developed his theory of natural selection in 1838 and set it forth in two unpublished sketches of 1842 and 1844. Then, never doubting his theory for a moment, but afraid to expose its revolutionary implications, he proceeded to stew, dither, wait, ponder, and collect data for another fifteen years. Finally, at the virtual insistence of his closest friends, he began to work on his notes, intending to publish a massive tome that would have been four times as long as the *Origin of Species*.

But in 1858 Darwin received a letter and manuscript from a young naturalist, Alfred Russel Wallace, who had independently constructed the theory of natural selection while lying ill with malaria on an island in the Malay

**36395. BLACK HOLES, QUASARS AND THE UNIVERSE.** *Henry L. Shipman.* An absorbing exploration of the frontiers of astronomy. **$15.50**

**74300-2. ROME AND HER EMPIRE.** *Barry Cunliffe.* A magnificently illustrated volume that makes the history of one of the world's greatest civilizations come alive. *Counts as 2 of your 3 books.* **$50.00**

**63217. MURMURS OF EARTH.** *Carl Sagan et al.* The story of the recorded messages carried by the *Voyager* space probe, man's first attempt at interstellar communication. **$15.00**

**54995. THE ILLUSTRATED ENCYCLOPEDIA OF ARCHAEOLOGY.** *Glyn Daniel.* **$17.95**

**32900-2. AMERICAN RIVERS.** *Bill Thomas.* An exciting textual and magnificent photographical exploration. *Counts as 2 of your 3 books.* **$30.00**

**61610. MAYA: The Riddle and Rediscovery of a Lost Civilization.** Charles Gallenkamp. **$15.95**

**82771. TEMPLES, TOMBS AND HIEROGLYPHS/RED LAND, BLACK LAND.** 2 excellent introductions to the complex and fascinating subject of Egyptian history. *The two count as one book.* **$25.90**

**73939. THE RESTLESS UNIVERSE/WHITNEY'S STAR FINDER.** *The two count as one book.* **$21.90**

**41510-2. THE DANCE, ART, AND RITUAL OF AFRICA.** *Michel Huet, et al.* A spectacular, outsize volume which records the pageants and rituals of Africa in more than 250 magnificent photographs. *Counts as 2 of your 3 books.* **$35.00**

**34210. THE ARCHAEOLOGY OF NORTH AMERICA.** *Dean Snow.* Prehistoric Indian cultures, from the first crossings into this continent to the 20th century. 195 photos, charts and maps. **$18.95**

**35506. BACKPACKING EQUIPMENT BUYER'S GUIDE/WALKING SOFTLY IN THE WILDERNESS: The Sierra Club Guide to Backpacking/ SIMPLE FOODS FOR THE PACK.** *Softcover. The 3 count as one book.* **$19.85**

**56208. AN INTRODUCTION TO ANCIENT EGYPT.** *T.G.H. James.* Explores art, history, religion and culture of ancient Egypt—from pre-dynastic Badarian farmers to the deaths of Antony and Cleopatra in 30 B.C. 100 black-and-white photos, 20 full-color plates. **$20.00**

**79975. THE SPOTTER'S GUIDES TO BIRDS, TREES, WILDFLOWERS, ROCKS & MINERALS, SHELLS, AND THE NIGHT SKY.** Six compact field guides, each illustrated in full color. **$23.70**

**63350. MYSTERIES OF THE MEXICAN PYRAMIDS.** *Peter Tompkins.* Stunning array of 500 photos, drawings and maps illustrates the fascinating Mesoamerican pyramids which have mystified archaeologists and laymen for centuries. **$20.00**

**44930-2. THE ENCYCLOPAEDIA OF IGNORANCE.** Fascinating encyclopedic exploration of the frontiers of scientific research. 58 internationally renowned scientists highlight topics ranging from evolution to black holes. *Counts as 2 of your 3 books.* **$30.00**

**77570. THE SECRET OF ATLANTIS.** *Otto Muck.* A dramatic re-creation of the life and death of Atlantis, which as Muck postulates, was destroyed in the course of a single day by a cosmic explosion of unparalleled proportions. **$12.50**

**77579-2. SECRETS OF THE ICE AGE/THE CAVE ARTISTS.** Vividly re-creates the life, environment and habits of Upper Paleolithic man. *Plus* explores the craft, styles and meaning of prehistoric cave art. Both books beautifully illustrated. *Counts as 2 of your 3 books.* **$31.90**

**87890-2. WORLD PREHISTORY IN NEW PERSPECTIVE.** *Grahame Clark.* Enormous, global survey of *all* civilizations from the first palaeolithic gatherings to the Aztecs. *Counts as 2 of your 3 books.* **$29.95**

**37353. CATALOGUE OF THE UNIVERSE.** *Paul Murdin, et al.* Three volumes in one: an atlas, encyclopedia, and book of descriptive astronomy. **$15.95**

**34730. THE ATLAS OF EARLY MAN.** *Jacquetta Hawkes.* A panoramic overview of concurrent events in history through charts, graphs, and illustrations, from prehistory to the Roman Empire. **$20.00**

Archipelago. Darwin was stunned by the detailed similarity. Wallace even claimed inspiration from the same nonbiological source—Malthus's essay on population. Darwin, in great anxiety, made the expected gesture of magnanimity but devoutly hoped that some way might be found to preserve his legitimate priority. He wrote to Lyell: "I would far rather burn my whole book, than that he or any other man should think that I have behaved in a paltry spirit." But he added a suggestion: "If I could honorably publish, I would state that I was induced now to publish a sketch . . . from Wallace having sent me an outline of my general conclusions."

Lyell and Hooker took the bait and came to Darwin's rescue. While Darwin stayed home, mourning the death of his daughter from scarlet fever, they presented a joint paper to the Linnaean Society containing an excerpt from Darwin's 1844 essay, together with Wallace's manuscript. A year later, Darwin published his feverishly compiled "abstract" of the longer work—the *Origin of Species*. Wallace had been eclipsed.

Wallace has come down through history as Darwin's shadow. In public and private, Darwin was infallibly decent and generous to his younger colleague. He wrote to Wallace in 1870:

> I hope it is a satisfaction to you to reflect—and very few things in my life have been more satisfactory to me—that we have never felt any jealousy towards each other, though in one sense rivals.

Wallace, in return, was consistently deferential. In 1864, he wrote to Darwin:

> As to the theory of Natural Selection itself, I shall always maintain it to be actually yours and yours only. You had worked it out in details I had never thought of, years before I had a ray of light on the subject, and my paper would never have convinced anybody or been noticed as more than an ingenious speculation, whereas your book has revolutionized the study of Natural History, and carried away captive the best men of the present age.

This genuine affection and mutual support masked a serious disagreement on what may be the fundamental question in evolutionary theory—both then and today. How exclusive is natural selection as an agent of evolutionary change? Must all features of organisms be viewed as adaptations? Yet Wallace's role as Darwin's subordinate alter ego is so firmly fixed in popular accounts that few students of evolution are even aware that the two men ever differed on theoretical questions. Moreover, in the one specific area where their public disagreement is a matter of record—the origin of human intellect—many writers have told the story backward because they failed to locate this debate in the context of a more general disagreement on the power of natural selection.

All subtle ideas can be trivialized, even vulgarized, by portrayal in uncompromising and absolute terms. Marx felt compelled to deny that he was a Marxist, while Einstein contended with the serious misstatement that he meant to say "all is relative." Darwin lived to see his name appropriated for an extreme view that he never held—for Darwinism has often been defined, both in his day and in our own, as the belief that virtually all evolutionary change is the product of natural selection.

Darwin often complained, with uncharacteristic bitterness, about this misappropriation of his name. He wrote in the last edition of the *Origin* (1872):

> As my conclusions have lately been much misrepresented, and it has been stated that I attribute the modification of species exclusively to natural selection, I may be permitted to remark that in the first edition of this work, and subsequently, I placed in a most conspicuous position—namely, at the close of the Introduction—the following words: "I am convinced that natural selection has been the main but not the exclusive means of modification." This has been of no avail. Great is the power of steady misrepresentation.

England did house a small group of strict selectionists—"Darwinians" in the misappropriated sense—and Alfred Russel Wallace was their leader. These biologists attributed all evolutionary change to natural selection. They viewed each bit of morphology, each function of an organ, each behavior as a product of selection leading to a "better" organism. They held a deep belief in nature's "rightness," in the exquisite fit of all creatures to their environments. In a curious sense, they almost reintroduced the creationist notion of natural harmony by substituting an omnipotent force of natural selection for a benevolent deity.

Darwin, on the other hand, was a consistent pluralist gazing upon a messier universe. He saw much fit and harmony, for he believed that natural selection holds pride of place among evolutionary forces. But other processes work as well, and organisms display an array of features that are not adaptations and do not promote survival directly. Darwin took particular interest in two principles leading to nonadaptive change: (1) Organisms are integrated systems and adaptive change in one part can lead to nonadaptive modifications of other features ("correlations of growth" in Darwin's phrase); (2) An organ built under the influence of selection for a specific role may be able, as a consequence of its structure, to perform many other, unselected functions as well.

Wallace stated the hard, hyperselectionist line—"pure Darwinism" in his terms—in an early article of 1867, calling it "a necessary deduction from the theory of natural selection."

> None of the definite facts of organic selection, no special organ, no characteristic form or marking, no peculiarities of instinct or of habit, no relations between species or between groups of species, can exist but which must now be, or once have been, useful to the individuals or races which possess them.

Indeed, he argued later, any apparent nonutility must only reflect our faulty knowledge—a remarkable argument since it renders the principle of utility impervious to disproof *a priori*:

> The assertion of "inutility" in the case of any organ . . . is not, and can never be, the statement of a fact, but merely an expression of our ignorance of its purpose or origin.

All the public and private arguments that Darwin pursued with Wallace centered upon their differing assessments of the power of natural selection. They first crossed swords on the issue of "sexual selection," the subsidiary process that Darwin had proposed to explain the origin of features that appeared to be irrelevant or even harmful in the usual "struggle for existence" (expressed primarily in feeding and defense), but that could be interpreted as devices for increasing success in mating—elaborate antlers of deer, or tail feathers of peacocks, for example. Darwin proposed two kinds of sexual selection: competition among males for access to females and choice exercised by females themselves. He attributed much of the racial differentiation among modern humans to sexual selection, based upon the different criteria of beauty that arose among various peoples. (His book—*The Descent of Man and Selection in Relation to Sex*

# Trees. Cash crop or natural monument?

If you're like most of us, the question splits your mind.

One side sees trees as beautiful, living things, while the other sees them as a crop that yields needed jobs and useful products.

Clearly, they are both. Some of them should be left alone. Others should be farmed. And therein lies a paradox.

The best way to leave the greatest number of trees to nature is to intensify the farming of the rest.

Farming trees is no different than farming wheat. Board feet per acre or bushels per acre, productivity is crucial. That's why we use scientific farming techniques to breed, sow, grow and harvest our trees.

As a result, we expect to double the yields from our southern timberlands by the turn of the century, and to boost them 15-20% elsewhere by 1985.

If we're successful, we can provide needed jobs, wood and paper products and thriving trees.

Reason enough to try, don't you think?

*(Approx. 14" diam., 4½" D.)*

The Round-Top Schoolhouse Clock
$120.00
*(Approx. 22"H. 13"W 4½" D.)*

We urge you to take heed while you still have the chance to obtain one of these *genuine* Antique Clocks at low, low prices you may never see again. Yes, at prices less than you'd pay for mere reproductions. Our clocks are authentic circa 1900 antiques, the kind that once ticked happily away in the schoolrooms, legal offices, railroad stations, pubs, front parlours and general stores of America's childhood. Lovingly restored and in 100% running order. Each is unique—yours will be numbered, registered to your family or whomever you designate and accompanied by a handsome Certificate of Age and Ownership (suitable for framing). Order now to avoid disappointment. When these clocks are gone, they're gone forever.

- Certificate of age, authenticity and ownership.
- Fully re-conditioned 8-day keywind movement, brass pendulum, key. Counts hour in melodic tones.
- Sturdily cartoned and shipped to you UPS insured. (Clocks will vary slightly in trim and wood tone.)

**For multiple orders use separate sheet of paper.**

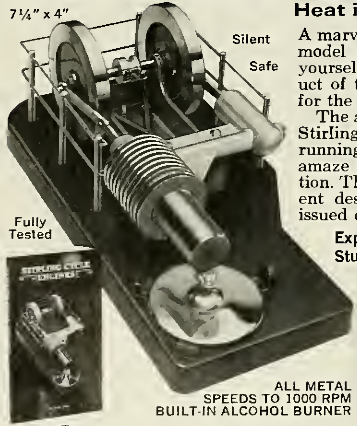
*The Amazing Stirling Cycle* **Hot Air Engine**

**Heat is the only fuel required!**

7¼" x 4"



A marvelous opportunity to acquire an early model Stirling Cycle Engine and acquaint yourself with little known facts about a product of the past that may well hold promise for the future.

The average person has never heard of the Stirling engine, so the sight of one quietly running with heat as its only fuel will at first amaze them and then excite their imagination. This is the first in a family of six different desk-top model hot air engines to be issued during the next three years.

**Experimenters • Hobbyists' Power Source**
**Students • Collectors • Model Engineers**

An easily read, lavishly illustrated, 128-page book accompanies each engine or may be purchased separately. This publication, the first of its kind, takes the reader on a 160-year tour through the world of Stirling Cycle Engines. Illustrations include the Stirling, Roper, Heinrici and the amazing new Stirling-powered Ford Torino!

[1871]—is an amalgam of two works: a long treatise on sexual selection throughout the animal kingdom and a shorter, speculative account of human origins, relying heavily upon sexual selection.)

The notion of sexual selection is not really contrary to natural selection, for it is just another route to the Darwinian imperative of differential reproductive success. But Wallace disliked sexual selection for three reasons: it compromised the generality of that peculiarly nineteenth-century view of natural selection as a battle for life itself, not merely for copulation; it placed altogether too much emphasis upon the "volition" of animals, particularly in the concept of female choice; and most importantly, it permitted the development of numerous, important features that are irrelevant, if not actually harmful, to the operation of an organism as a well-designed machine. Thus, Wallace viewed sexual selection as a threat to his vision of animals as works of exquisite craftsmanship, wrought by the purely material force of natural selection. (Indeed, Darwin had developed the concept largely to explain why so many differences among human groups are irrelevant to survival based upon good design, but merely reflect the variety of capricious criteria for beauty that arose for no adaptive reason among various races. In the end, Wallace did accept sexual selection based upon male combat as close enough to the metaphor of battle that controlled his concept of natural selection. But he firmly rejected the notion of female choice and distressed Darwin with his speculative attempts to attribute all features based upon it to the adaptive action of natural selection.)

As he prepared the *Descent of Man*, Darwin wrote to Wallace in 1870: "I grieve to differ from you, and it actually terrifies me and makes me constantly distrust myself. I fear we shall never quite understand each other." He struggled to understand Wallace's reluctance and even to accept his friend's faith in unalloyed natural selection: "You will be pleased to hear," he wrote to Wallace,

> that I am undergoing severe distress about protection and sexual selection; this morning I oscillated with joy towards you; this evening I have swung back to [my] old position, out of which I fear I shall never get.

But the debate on sexual selection was merely a prelude to a much more serious and famous disagreement on that most emotional and contentious subject of all—human origins. In short, Wallace, the hyperselectionist, the man who had twitted Darwin for his unwillingness to see the action of natural selection in every nuance of organic form, halted abruptly before the human brain. Our intellect and morality, Wallace argued, could not be the product of natural selection; therefore, since natural selection is evolution's only way, some higher power—God, to put it directly—must have intervened to construct this latest and greatest of organic innovations.

If Darwin had been distressed by his failure to impress Wallace with sexual selection, he was positively aghast at Wallace's abrupt about-face at the finish line itself. He wrote to Wallace in 1869: "I hope you have not murdered too completely your own and my child." A month later, he remonstrated: "If you had not told me, I should have thought that [your remarks on Man] had been added by some one else. As you expected, I differ grievously from you, and I am very sorry for it." Wallace, sensitive to the rebuke, thereafter referred to his theory of human intellect as "my special heresy."

The conventional account of Wallace's apostasy at the brink of complete consistency cites a failure of courage to take the last step and admit man fully into the natural system—a step that Darwin took with commendable fortitude in two books, the *Descent of Man* and *The Expression of the Emotions in Man and Animals* (1872). Thus, Wallace emerges from most historical accounts as a lesser man than Darwin for one (or more) of three reasons, all related to his position on the origins of human intellect: for simple cowardice; for inability to transcend the constraints of culture and traditional views of human uniqueness; and for inconsistency in advocating natural selection so strongly (in the debate on sexual selection), yet abandoning it at the most crucial moment of all.

I cannot analyze Wallace's psyche and will not comment on his deeper motives for hewing to the unbridgeable gap between human intellect and the behavior of mere animals. But I can assess the logic of his argument and recognize that the traditional account is not only incorrect, but precisely backward. Wallace did not abandon natural selection at the human threshold. Rather, it was his peculiarly rigid view

of natural selection that led him, quite consistently, to reject it for the human mind. His position never varied—natural selection is the only cause of major evolutionary change. His two major debates with Darwin—sexual selection and the origin of human intellect—represent the same argument, not an inconsistent Wallace championing selection in one case and running from it in the other. Wallace's error on human intellect arose from the inadequacy of his rigid selectionism, not from a failure to apply it. And his argument repays our study today, since its flaw remains as the weak link in many of the most "modern" evolutionary speculations of our current literature. For Wallace's rigid selectionism is much closer than Darwin's pluralism to the attitude embodied in our favored theory today, which, ironically in this context, goes by the name of Neo-Darwinism.

Wallace advanced several arguments for the uniqueness of human intellect, but his central claim begins with an extremely uncommon position for his time, one that commands our highest praise in retrospect. Wallace was one of the few nonracists of the nineteenth century. He really believed that all human groups had innately equal capacities of intellect. Wallace defended his decidedly unconventional egalitarianism with two arguments, anatomical and cultural. He claimed, first of all, that the brains of "savages" are neither much smaller nor more poorly organized than our own:

> In the brain of the lowest savages, and, as far as we know, of the prehistoric races, we have an organ . . . little inferior in size and complexity to that of the highest type.

Moreover, since cultural conditioning can integrate the rudest savage into our most courtly life, the rudeness itself must arise from a failure to use existing capacities, not from their absence:

> It is latent in the lower races, since under European training native military bands have been formed in many parts of the world, which have been able to perform creditably the best modern music.

Of course, in calling Wallace a nonracist, I do not mean to imply that he regarded the cultural practices of all peoples as equal in intrinsic worth. Quite the contrary. Wallace, like most of his contemporaries, was an ardent cultural chauvinist who never doubted the evident superiority of European ways. He may have been bullish on the

**GUAYABERA SHIRT:** For decades the GUAYABERA shirt has been synonymous with graceful and casual living in Latin America. The elegant design and casually free tailoring will insure confidence in your dress and appearance turning a simple evening into an event.

**Intricate design** — The front and back of the shirt have 3 pleats. Each pleat is formed with 6 double stitched folds with a ¼ inch plain stripe in the middle for balance. The bottoms of the shirt and sleeves have an inch and a half border with buttons.

**4 pockets** — are wide and deep allowing you to carry otherwise bulky materials with ease and grace. The unflapped pockets are double stitched.

**Comfortable fit** — the GUAYABERA is designed to wear loosely allowing maximum freedom of movement. The free hanging shirt has two side vents with 3 slits which may be unbuttoned to adjust to your particular build. As the evening wears on the 65% dacron — 35% cotton GUAYABERA will keep its shape and fresh look.

Smaller can be better, as the new full-power Nikon Roof Prism Compact Binoculars clearly demonstrate. Pocket-size slim and just 7-1/2 ounces light, they outperform many bigger and heavier binoculars in sharp, bright, distortion-free viewing. You see the entire scene, even while wearing glasses. And, most important, they're so precisely engineered that you can view for extended periods, without strain or discomfort. Available in all-purpose 6x, 7x and 8x models. See the difference Nikon quality makes, at Nikon camera dealers and selected optical departments. Or write to Nikon Inc., Dept. N-26, Garden City, New York 11530.

capability of savages, but he certainly had a low opinion of their life, as he mistook it:

> Our law, our government, and our science continually require us to reason through a variety of complicated phenomena to the expected result. Even our games, such as chess, compel us to exercise all these faculties in a remarkable degree. Compare this with the savage languages, which contain no words for abstract conceptions; the utter want of foresight of the savage man beyond his simplest necessities; his inability to combine, or to compare, or to reason on any general subject that does not immediately appeal to his senses.

Hence, Wallace's dilemma: all savages, from our actual ancestors to modern survivors, had brains fully capable of developing and appreciating all the finest subtleties of European art, morality and philosophy; yet they used, in the state of nature, only the tiniest fraction of that capacity in constructing their rudimentary cultures, with impoverished languages and repugnant morality.

But natural selection can only fashion a feature for immediate use. The brain is vastly overdesigned for what it accomplished in primitive society; thus, natural selection could not have built it:

> A brain one-half larger than that of the gorilla would . . . fully have sufficed for the limited mental development of the savage; and we must therefore admit that the large brain he actually possesses could never have been solely developed by any of those laws of evolution, whose essence is, that they lead to a degree of organization exactly proportionate to the wants of each species, never beyond those wants. . . . Natural selection could only have endowed savage man with a brain a few degrees superior to that of an ape, whereas he actually possesses one very little inferior to that of a philosopher.

Wallace did not confine this general argument to abstract intellect, but extended it to all aspects of European "refinement," to language and music in particular. Consider his views on "the wonderful power, range, flexibility, and sweetness of the musical sounds producible by the human larynx, especially in the female sex."

> The habits of savages give no indication of how this faculty could have been developed by natural selection, because it is never required or used by them. The singing of savages is a more or less monotonous howling, and the females seldom sing at all. Savages certainly never choose their wives for fine voices, but for rude health, and strength, and physical beauty. Sexual selection could not therefore have developed this wonderful power, which only comes into play among civilized people. It seems as if the organ had been prepared in anticipation of the future progress in man, since it contains latent capacities which are useless to him in his earlier condition.

Finally, if our higher capacities arose before we used or needed them, then they cannot be the product of natural selection. And if they originated in anticipation of a future need, then they must be the direct creation of a higher intelligence: "The inference I would draw from this class of phenomena is, that a superior intelligence has guided the development of man in a definite direction, and for a special purpose." Wallace had rejoined the camp of natural theology. Darwin remonstrated, but failed to budge his partner.

The fallacy of Wallace's argument is not a simple unwillingness to extend evolution to humans, but rather the hyperselectionism that permeated all his evolutionary thought. For if hyperselectionism is valid—if every part of every creature is fashioned for and only for its immediate use—then Wallace cannot be gainsaid. The earliest Cro-Magnon people, with brains bigger than our own, produced stunning paintings in their caves, but did not write symphonies or build computers. All that we have accomplished since then is the product of cultural evolution based on a brain of unvarying capacity. In Wallace's view, that brain could not be the product of natural selection, since it could always do so much more than it did in its original state.

But hyperselectionism is not valid. It is a caricature of Darwin's subtler view, and it both ignores and misunderstands the nature of organic form and function. Natural selection may build an organ "for" a specific function or group of functions. But this purpose need not fully specify the capacity of a structure. Objects designed for definite purposes can, as a result of their structural complexity, perform many other tasks as well. A factory may install a computer only to issue the monthly pay checks, but such a machine can also analyze the election returns or whip anyone (or at least perpetually tie them) in tick-tack-toe. Our large brains may have originated for some set of necessary skills in gathering food, socializing, or whatever; but these skills do not exhaust the limits of what such a complex machine can do. Fortunately for us, those limits in-

## Make this a year to remember—the year your child's mind and heart is opened to the Story of America.™

**History is more than dates. It's people, events, movements and institutions. It's political thought, religious beliefs, economic forces and cultural yearnings.**

**Scholars often study for years to understand them. But sometimes a few well-chosen words and the right picture cast a brilliant light on the subject . . . and understanding comes in a flash!**

Thousands of Americans, adults and children, are suddenly discovering America this way—through Story of America Cards. We'd like to send you 24 of them for just $1.00!

Plus a second set of 24 cards *free* (that's 48 in all). Plus the 600-card collector's file case *free*. Plus 16 file organizers *free*. Plus an 8-page color booklet, "Panorama of History," *free*. All to give your discovery of America a glorious head start.

Your collection entertains as it instructs. Each card has a full color illustration on the front and an informative, concise text on the back. And, as your collection grows, so does its usefulness. It quickly becomes a lively encyclopedia of American history you can turn to for looking up facts or researching ideas.

You can file your cards in several ways: chronologically, by subject, or by broad category. And this is additional educational enrichment, for it teaches children how to organize data.

Some children can learn history classroom-style with intensive cramming, but it's easier "picnic-style"—where they can nibble at whatever appeals, without biting more than they can chew.

Send today for our start-up package. It's a $9 value—yours at the introductory price of just $1.00 (details are in the coupon). There's no risk—if you're not satisfied you simply return the cards to get your dollar back.

**24 Story of America Cards $1.00 plus $8.00 worth of GIFTS**

clude, among other things, an ability to write—from shopping lists for all of us to grand opera for a few. And our larynx may have arisen for a limited range of articulated sound needed to coordinate social life. But its physical design permits us to do more with it—from singing in the shower for all to the occasional diva.

Hyperselectionism has been with us for a long time in various guises, for it represents the late-nineteenth-century's scientific version of the myth of natural harmony—all structures well designed for a definite purpose. It is, indeed, the vision of foolish Dr. Pangloss, so vividly satirized by Voltaire in *Candide*—"all is for the best in the best of all possible worlds." As the good doctor said in a famous passage, which predated Wallace by a century, but captures the essence of what is so deeply wrong with his argument:

> Things cannot be other than they are. . . . Everything is made for the best purpose. Our noses were made to carry spectacles, so we have spectacles. Legs were clearly intended for breeches, and we wear them.

Nor is Panglossianism dead today—not when so many books in the pop literature on human behavior state that we evolved our big brain for hunting, then trace all our current ills to limits of thought and emotion supposedly imposed by such a mode of life.

Ironically then, Wallace's hyperselectionism led right back to the basic belief of an earlier creationism that it meant to replace—a faith in the rightness of things, a definite place for each object in an integrated whole. As Wallace wrote, quite unfairly, of Darwin:

> He whose teachings were at first stigmatized as degrading or even atheistical, by devoting to the varied phenomena of living things the loving, patient, and reverent study of one who really had faith in the beauty and harmony and perfection of creation, was enabled to bring to light innumerable adaptations, and to prove that the most insignificant parts of the meanest living things had a use and a purpose.

I do not deny that nature has its harmonies. But structure also has its latent capacities. Built for one thing, it can do others—and in this flexibility lies both the messiness and the hope of our lives.

*Stephen Jay Gould teaches biology, geology, and the history of science at Harvard University.*

# THE ILLINOIS STATE MUSEUM presents this summer 3 field study tours in ARCHAEOLOGY & GEOLOGY

*Olduvai Gorge in Tanzania contains some of the oldest fossil remains of Early Man. A day at this site with Dr. Mary Leakey is being planned in August.*

## FIELD GEOLOGY OF THE GRAND CANYON

**June 23 to July 2, 1980**

A 10-day and 300-mile raft trip through the Grand Canyon on the Colorado River, longest and fastest whitewater river in the country. Study of the first 1½ billion years of Colorado Plateau history. Then, on to scenic Zion and Bryce canyons to study the remaining 250 million years for this region for the last 3 days.

## EXCAVATION PROGRAM IN ARCHAEOLOGY AND VERTEBRATE PALEONTOLOGY

**July 12 to July 25, 1980**

Sites being excavated by research scientists and participants of this program at Kampsville, Illinois and at Kimmswick and Barnhart, Missouri. Kampsville archaeological excavations are Late Woodland and Mississippian (AD 400-1400); those at Kimmswick and Barnhart are Late Pleistocene. An 11,000-year-old Clovis projectile point, the earliest type manufactured by Indians of North America, was found in close association with mastodon and other Ice Age animals at Kimmswick.

## AN EAST AFRICAN GEOLOGICAL SAFARI

**August 7 to August 28, 1980**

Kilimanjaro; Olduvai Gorge; Rift Valley; the Serengeti. All well known features of East Africa. During this in-depth field study program, these, as well as other areas of geologic interest in Kenya and Tanzania, will be visited. Opportunities to collect fine mineral, crystal, and fossil specimens are provided. In the great game reserves—Amboseli, Tsavo, Ngorongoro, Serengeti—the horizon-to-horizon herds of wildebeest and zebra in migration, prides of lion and herds of elephant, or the solitary cheetah and leopard, will be captured on film. On safari, the peoples of East Africa, especially the Masai and Kikuyu, become familiar companions.

All programs arranged and directed by Christopher J. Schuberth, Curator of Education and Geologist at the Museum. For further information and detailed brochures, write or telephone immediately:

# GOLD of EL DORADO

## THE HERITAGE OF COLOMBIA

...is art and design
...is history and archeology
...is astounding prehistoric technology
...is breathtaking treasures

The unprecedented exhibition of 500 gold objects—from breastplates, statuettes and face masks to fantasy figures, sacred symbols and fishhooks—premiered November 13, 1979, at the American Museum of Natural History. It is one of the major cultural events in New York City this winter.

The national tour of "Gold of El Dorado" is sponsored by Chemical Bank, with additional support from the National Endowment for the Humanities and the Federal Council on the Arts and Humanities.

Gold of El Dorado: November 13, 1979, through March 18, 1980

The Museum, as always, will endeavor to give special treatment to its nearly half million dedicated members. Tickets, which allow members and their guests priority entrance to the exhibition, have been mailed to all members in the Greater New York metropolitan region. Members living outside the metropolitan region who would like to see this exhibition should write us at

"I think the best $200,000 Gulf ever spent was for this seagoing vacuum cleaner."
Gulf

"In the last year or so, Gulf O has spent about $250 million to protect the environment around Gulf drilling rigs, mines and refineries," says Manuel Andino, Gulf's Utilities Director at San Juan, Puerto Rico.

*"If any oil gets into the water, the Bay Skimmer can pick it up fast."*

"But I'd say the Bay Skimmer was one of their best investments $200,000 for a seagoing vacuum cleaner for San Juan Harbor.

"We've had a refinery here for 25 years. About 15 million barrel of Gulf crude oil and refined products pass through this port each year.

"That's a lot of oil, and if *any* it gets into the water, the Bay Skimmer can pick it up fast. It w tailor-made for this job. We can g right through an oil slick, and a b belt in the bow simply lifts the oi off the water.

"The Bay Skimmer is just one detail in Gulf's overall investmen in protecting the environment while keeping the oil flowing. Responsible energy management is a big challenge. It's expensive and it's complex. But it's a job wor doing, and I think we're doing it right."

# Powerful Nature

# Powerful Magazine

Powerful Nature can be large—a whale, a redwood tree, an erupting volcano. Or small—this simple, orange-feathered sea animal called a crinoid.

500 million years ago, give or take a few million, the ancestors of this colorful creature flourished throughout the earth's oceans. So much so, in fact, that their fossilized remains covered hundreds of miles of ancient sea bottom with a limestone layer 100 feet thick.

By Nature's reckoning, it's hardly remarkable that an animal lived half a billion years ago. What's so extraordinary about these unsinkable survivors is that they're still very much with us today—looking and living almost exactly as they did then!

## What makes a magazine powerful?

If you had to be big to be powerful, nobody would ever have heard of *The New Yorker.*

If mass editorial appeal were essential, *Scientific American* would have disappeared long ago.

NATURAL HISTORY

Then what determines a magazine's power—its value for advertisers? Two things alone. The buying inclinations of its readers. And the magazine's ability to influence them.

## Powerful readers, powerfully attracted.

*Natural History* readers are wonderful prospects. As their advanced education, lofty job titles, and enviable average income can testify.

They come to us because they're devoted to the natural sciences. And so are we.

The natural sciences go by a formidable array of names—biology, zoology, entomology, anthropology, and dozens more. But reduced to their basics, the natural sciences are the study of everything that's living now, or has ever lived on earth.

## A celebration of life.

Readers identify with *Natural History* because we're the only magazine that covers the natural world they find so fascinating. The only magazine that mirrors their own pleasure in exploring the myriad forms of life that co-exist under Nature's umbrella.

Man, too, is part of Nature—perhaps the most important, and certainly the liveliest part of all. *Natural History* observes people in all their rich variety. From the tribal customs of South Sea islanders to the tribal customs of Jamaicans living in Brooklyn. From young drummers in Africa to aging Jews in California. Revealing glimpses of man's impact on himself and his environment.

## A climate of mutual respect.

In some magazines, scientific articles are written by journalists who've learned just enough to stay one jump ahead of their readers.

In *Natural History*, scientific articles are written by scientists who can write. Like biologist David Meyer, co-author of the engaging article on crinoids. During his research, Dr. Meyer has made more than 800 scuba dives in the Caribbean and the Pacific. He writes with authority. And our readers can tell.

*Natural History* readers are smart enough to know when they're being talked down to. So we never do. Our authors are asked to write, not to suit a mass audience taste, but as though they were writing about their work to a respected colleague in another field.

With a style like ours, *Natural History* will never be as big as *Time*. But we have a power even much larger magazines can never have. A power that enlivens our pages, intrigues our readers, and benefits our advertisers.

The power of Nature.

**More power to you.**

# Desert Shrewd

*To survive in the desert, a tiny mammal must venture forth at night, conserve its water, and eat like mad*

**by Stan L. Lindstedt and James H. Jones**
**photographs by Raymond A. Mendez**

The deserts of the southwestern United States test, in a number of ways, an animal's ability to survive. The parched land has little or no free water, and air temperatures during summer days may exceed 120°F. Only animals that can tolerate or avoid such heat, and that are especially adept at conserving water, survive.

Paradoxically, among the desert dwellers there lives an animal whose closest relatives are found almost exclusively in lush, moist habitats. The paradox is deepened by this animal's size and diet, which suggest a minimal tolerance of high temperatures and an extreme need for water. It is the smallest mammal living in any of the world's deserts—the desert shrew.

This tiny mammal is found throughout the southwestern United States and northern Mexico, inhabiting parts of the Sonoran, Chihuahuan, Mojave, and Great Basin deserts. Although they may be abundant in some areas, desert shrews are rarely encountered by biologists. Much of the information about their distribution has come, not from firsthand observations, but from bones recovered in owl pellets. In addition to being the smallest desert mammal, the desert shrew is also one of the world's smallest homoiotherms (animals that maintain a constant body temperature). The animal measures only about one and a half inches in length (about half of which is tail) when fully grown, and ranges in weight from less than three grams (the weight of a penny) to five grams (the weight of a nickel).

Desert shrews are born during the summer in litters of three to six. Naked, pink, and about the size of honeybees, newborns grow rapidly, and after two weeks their combined weight may be twice that of their mother. For her size, the mother produces milk at a rate that must be a mammalian record—and she does it without drinking water. Two to three weeks after birth, the babies' diet is supplemented in a manner formerly believed to be unique, among mammals, to canids. Food is brought back to the nest and regurgitated into the mouths of the young. The shrews reach adult size in four to five weeks and are out of the nest and on their own by the time the first cold nights of fall arrive.

Shrews are in the mammalian order Insectivora. Because their diet includes great numbers of insects, they consume large amounts of protein. The waste product of protein digestion is nitrogen, which is excreted in urine as urea. If their kidneys could concentrate urine no more than the kidneys of other shrews, desert shrews would require several times their actual daily water intake just to relieve themselves of urea.

While the desert shrew's potential for urinary water loss is great, other water losses could be even greater. To maintain a constant body temperature

*Gnawing on the tail of a bunch grass lizard, a desert shrew begins to feast on prey larger than itself. The lizard was asleep under an agave, where the shrew discovered and dispatched it.*

of about 99°F, they must use some water for evaporative cooling. Unless heat is lost by the evaporation of water, the body temperature of an animal in a hot environment will increase until it equals that of its surroundings. In some mammals, such as humans, evaporative cooling takes the form of sweating; in shrews and many other mammals it is accomplished by panting. As long as enough water is available, evaporative cooling can maintain body temperature within tolerable limits.

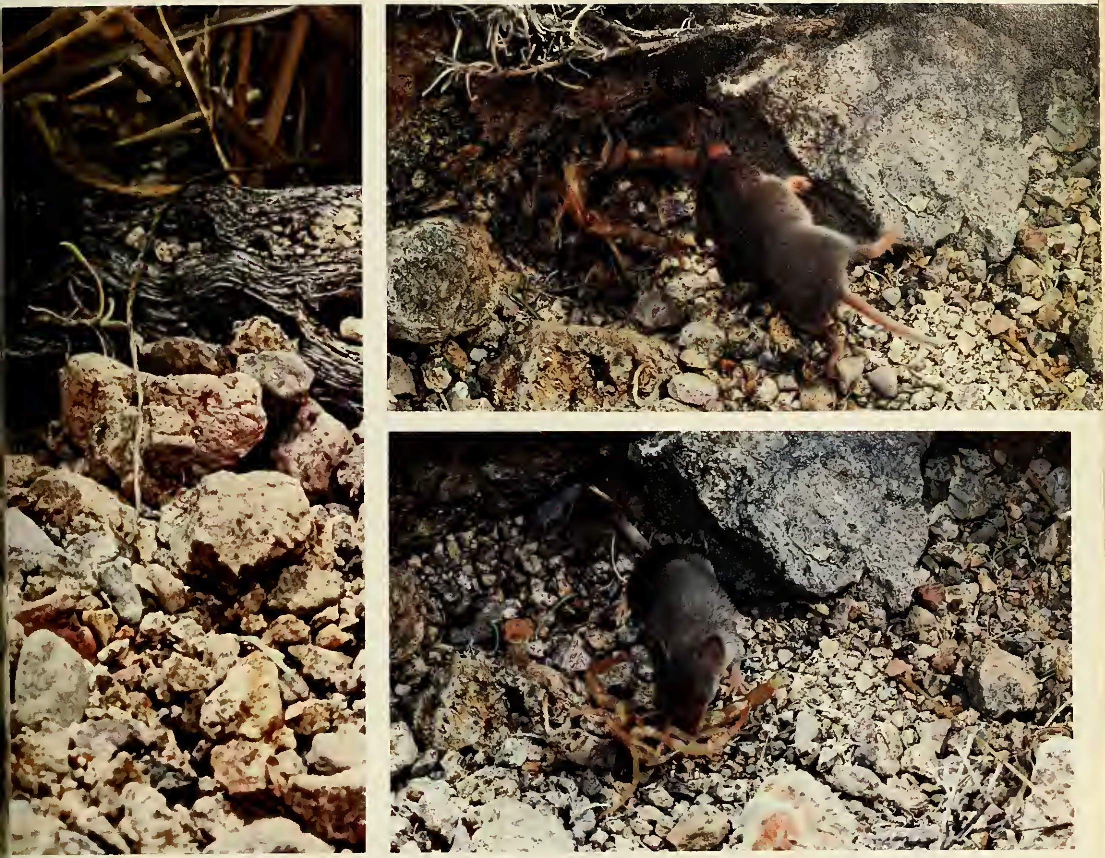
The rate of heat exchange is proportional both to the difference in temperature between the animal and its environment and to the body size of the animal. Just as a spoonful of soup heats or cools more rapidly than a bowlful, so the body temperatures of the smallest animals are most sensitive to the thermal environment surrounding them. An animal or object exchanges heat with its surroundings at a rate proportional to its surface area, while its capacity to store heat is proportional to its mass. The smallest animals have a large area for heat exchange and a small body mass; therefore they heat and cool rapidly. An animal with a small body mass, such as a shrew, must evaporate water at a much faster rate (for its size) than a larger-bodied animal when both are in the same hot environment.

This relationship between body size and the rate of heat exchange is also a liability for small animals in the cold—a smaller body cools faster when the temperature is below body temperature. As a result, smaller animals produce more heat per unit body mass than larger animals. If it had the same metabolic rate as a cow, an animal the size of a one-inch shrew would need eight inches of fur to keep warm at room temperature; conversely, a cow's body temperature would exceed the boiling point of water if it produced metabolic heat as rapidly as a shrew.

To maintain such a high rate of metabolism, shrews must consume a great deal of food for fuel. This high food intake is the basis for the legend that a "shrew eats its own weight in food each day." In fact, many do. However, the shrew's high metabolic rate, necessary for it to keep warm in low air temperatures, becomes a liability when the temperature is high. A shrew in a hot desert faces overheating when heat produced by its high metabolism is coupled with heat gained from the environment.

Its metabolism could cause yet another problem for the desert shrew—an increase in all of the body's functions, including respiration rates. Every rapid breath of dry desert air is saturated with water vapor from the moist lung surface. If all of this water were lost with each exhalation, the total water loss due to respiration would be considerable.

The potential water loss from all of



*Attacking a giant hairy scorpion, a desert shrew rushes in to bite the venomous arachnid, which raises its tail in a typical defense posture, left. Lashing out with its tail, the scorpion tries to sting its attacker, top. The shrew jumps easily out of the way and wins the battle by biting through the scorpion's tail, bottom.*

these sources would appear to vastly exceed the amount of water available to this nondrinking shrew through its insect diet. Since shrews are otherwise restricted to moist habitats that supply them with abundant water, desert shrews possess unique adaptations that allow them to survive in the dry habitat. Results from studies completed recently at the University of Arizona suggest how they surmount seemingly impossible obstacles.

Shrews do not construct burrows or use those of other animals, hence they are unable to avoid environmental extremes the way other small desert rodents do. Instead, they use grasses and other available vegetation to build nests that insulate them against severe external temperatures, and in so doing they conserve water. These nests, as small inside as one by one and a half inches, are frequently built inside pack rat houses or in leaf litter beneath dead agaves. Consequently, these shrews live in microhabitats that are mild relative to outside conditions. By this strategy, the desert shrew effectively exploits its tiny size to avoid an environmental stress that many larger animals must confront directly.

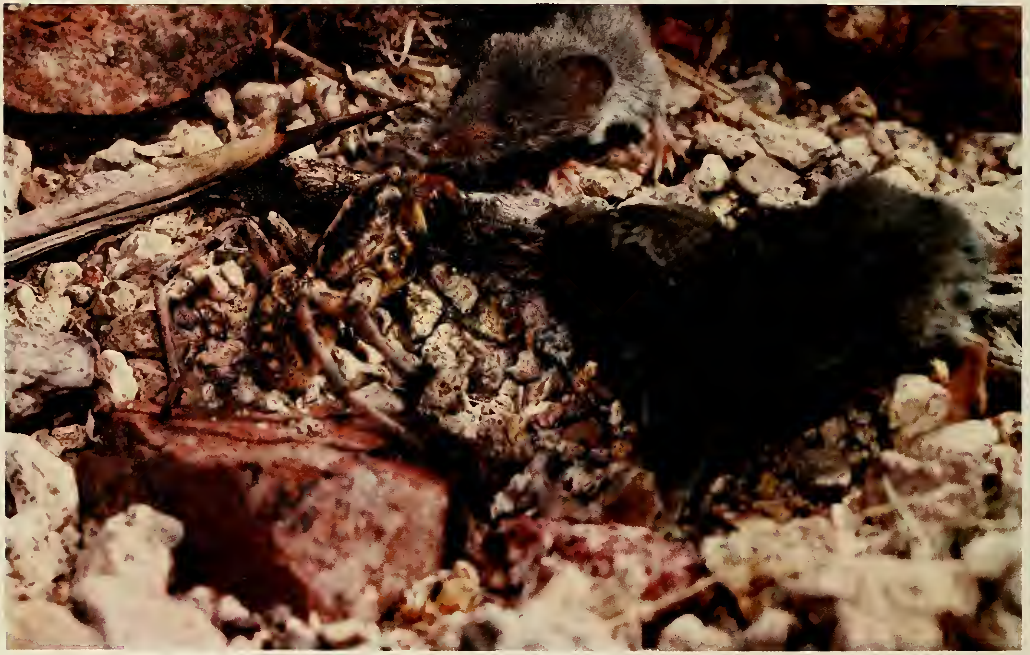
The desert shrew also conserves water by restricting most of its activities to the night. This behavior is uncommon among shrews, which usually hunt both day and night since they can starve to death in as few as four hours. The desert shrew's senses reflect its primarily nocturnal existence; although its vision is poor, its long nose and large ears appear to be extremely sensitive. In fact, the desert shrew has such well-developed external ears (rare among shrews) that it is occasionally referred to as the "eared shrew." It may also have some rudimentary ability to echolocate prey, utilizing high-frequency squeaks similar to the sophisticated sonar of bats, their near relatives. The ears probably also act as heat radiators, increasing the surface area for heat loss when the shrew is hot and in a suitable location to lose heat by this means.

Voracious and energetic hunters, desert shrews depend primarily on their acute hearing to locate prey. A shrew may leave its nest to forage and eat many times during the night, attacking almost any insect (including cockroaches, moths, grasshoppers, and grubs), arachnid, lizard, or rodent small enough for it to kill. Prey small enough for the shrew to kill is frequently larger than the shrew itself. If it comes across several insects at once, the desert shrew will dash about killing or incapacitating all of them and will stockpile the prey in its nest before eating. Desert shrews paralyze insects by carefully crushing their heads without killing them. Then, when they need to refuel after a few hours, their insect food is still alive and, more importantly, has lost little of the valuable moisture that would have been lost if the exoskeleton had been damaged. Shrews take the largest or most heavily armored insects by first biting off their legs, before delivering a head-crushing bite. With enough prey collected in the nest at night, the shrew has no need to expose itself to daytime heat.

Even though they manage to avoid the most extreme heat by staying in their nests, desert shrews still face a water shortage. An insect diet provides some water, but for desert shrews the key to survival is conserving what little water is available by using some specialized physiological adaptations.

The shrew maintains a positive water balance by considerably reducing two major avenues of water loss—urine and respiration. While its rapid breathing rate tends to increase water losses, a substantial fraction of the water vapor that would otherwise be exhaled is reclaimed through a remarkable arrangement of blood and air flow inside the desert shrew's nose. Inhaled air is warmed to body temperature and saturated with water vapor from the moist nasal walls. Exhaled air is cooled as it passes along the narrow nasal passage in the opposite direction to blood flow in the walls of the nose. This blood, previously cooled at the skin and nose surfaces before flowing along the nasal passage, absorbs heat from the exhaled air, thereby cooling it. As the air cools, much of its water vapor condenses on the walls of the nasal passage, just as dew and fog form when

*With large insects such as this praying mantis, a desert shrew first bites off enough legs to immobilize the victim. A head-crushing bite is the* coup de grâce.



warm, moist air cools during the night. The net result of this "countercurrent heat exchanger" is that the cooler exhaled air contains far less water vapor than if it were exhaled at body temperature.

Respiratory water loss is further reduced in these animals because they take fewer breaths relative to other shrews. Their low resting metabolic rate—the lowest of all shrew species—decreases passive respiratory water losses. Because they produce less internal heat, desert shrews need less water for evaporative cooling. Consequently, they can survive in air temperatures over 100°F, heat loads that would soon be fatal for other shrew species.

The shrew's other major avenue for potential water loss is through the urine because it must excrete a large amount of nitrogenous wastes. However, urinary water loss in the desert shrew is also reduced. By concentrating far more urea in the urine than most other mammals, the desert shrew saves valuable water. Urea is concentrated by the same physical principle that conserves water in the nose—a countercurrent system. However, in the kidney, instead of heat being exchanged, urea is concentrated along the length of extremely long tubes (nephrons), and the final urine is four times more concentrated than that of humans. Since only a few drops of concentrated urine are sufficient to remove all of the shrew's nitrogenous wastes each day, the result is a substantial savings of water for the animal. These few drops are used to cement the feces together in a characteristic fashion. A useful indicator that a desert shrew nest is nearby is one of these fairly conspicuous defecatoria, which are always in the immediate vicinity of the nest.

Another severe challenge to this animal's survival is presented by the often unpredictable periods of food scarcity. Birds can escape these periods by migration, and many desert rodents survive by hibernating or feeding on seed stores. Shrews, however, are not known to hibernate and they cannot store their perishable insect food for long. During the Sonoran Desert's two dry seasons, late spring and late fall, temperatures are mild, but insect abundance is often low. At those times, desert shrews spend the daytime hours in a state of torpor, during which their body temperature thermostat is reset about 20°F below its normal level. This "regulated hypothermia," unique among North American insectivores, allows the shrew to maintain a reduced metabolic rate and stretch its available energy reserves up to five times longer than would otherwise be possible.

Physiological and behavioral frugality have allowed the desert shrew, a member of a mammalian family normally restricted to cool, moist habitats, to survive in the hot North American deserts. Energy metabolism, water loss, and daytime activity are all lower in the desert shrew than in any other shrew species. Maintaining a strict economy of water and energy has allowed it to successfully exploit an environment that would be lethal to its closest relatives. The desert shrew's survival is a prime example of the need for conservation in an environment where resources are limited. ☐

*Two sibling shrews mount an attack against a wolf spider, above. They have already bitten off several legs, and the end is in sight. The spiders are virtually defenseless against these predators. Right, one of the shrews carries off the dead spider to its nest for later consumption. (The shrews are so fast that lights firing at 1/3,000 second cannot stop the action.)*

# BMW. THE CAR COMPANY THAT HASN'T BEEN LEGISLATED INTO MEDIOCRITY.

The challenge that faces the automaker of the 1980's lies not in meeting tougher pollution standards, nor in coping with ever more restrictive safety regulations—not even in accommodating the petroleum shortages that are fast becoming a regular summer occurrence.

No indeed. The challenge lies in meeting the myriad of societal demands and still building automobiles that are worth driving.

Pessimists darkly predict that it cannot be done and point to the depressing number of uninspired automobiles on the market as incontrovertible proof.

Yet, fortunately, these gloomy predictions do not take into account the inventive genius and the obsessive determination of the engineers at BMW in Munich, Germany to build extraordinary automobiles.

Against all odds the BMW not only meets the demands of

© 1979 BMW of North America, Inc. The BMW trademark and logo are registered trademarks of Bayerische Motoren Werke, A.G.

BMW
528i
BMW
320i

society, it also provides the sort of exhilarating driving experience that automotive enthusiasts have all but given up for lost.

## A SEEMINGLY INCONGRUOUS COMBINATION OF LUXURY, PERFORMANCE AND EFFICIENCY.

Conventional automotive wisdom has it that, inevitably, one must choose between luxury, performance and fuel efficiency. A sufficiency in any one necessitating a corresponding insufficiency in another.

And in the face of this, the BMW seems all the more remarkable for requiring no compromise whatsoever.

Round a particularly sticky curve and the legendary BMW suspension system—independent on all four wheels—flexes with an uncanny resiliency that makes one feel as if the car were built into the roadway. A sensation that results from highly advanced suspension technology and the virtually perfect integration of man and machine.

The BMW power plant—whether 4 or 6 cylinder—has long been a model for modern design. Press the accelerator and the fuel-injected, overhead cam engine responds in a manner that can only be described as exhilarating.

Yet, the 320i (with 5-speed standard transmission) delivers an impressive 25 EPA estimated mpg, 36 estimated highway mileage and, based on these figures, an estimated mpg range of 383 miles and a highway range of 551 miles.

(Naturally our fuel efficiency figures are for comparison purposes only. Your actual mileage and range may vary, depending on speed, weather and trip length. Your actual highway mileage and highway range will most likely be lower.)

And, while the BMW provides as long a list of luxury items as one could sanely require, its luxury is purposefully engineered to help prevent driver fatigue.

Vital controls are within easy reach; the tachometer, speedometer and ancillary instruments are well-marked and easy to read.

Its front seats are designed to hold their occupants firmly in place, and are so thoroughly adjustable that it is all but a mathematical impossibility not to find a comfortable seating position.

## SAFETY BEYOND STURDY BUMPERS.

At BMW, automotive safety was of primary concern long before the first bumper law was written.

The passenger compartment is encased in a solid steel "cage." So strong is this construction that the car could be dropped on its nose from the fourth floor of a building without significant damage to the compartment itself.

Yet with all its sheer strength—its computer-programmed "crush zones," its double-braking systems—the BMW features a safety device even more estimable.

Its exceptional responsiveness and handling characteristics give it the ability to avoid accidents as well as merely survive them.

All in all, in a time of lowered automotive expectations, amidst increasing mediocrity, the engineers at BMW have actually improved the BMW.

If you'd care to judge for yourself, telephone your nearest BMW dealer to arrange a thorough test drive at your convenience.

**THE ULTIMATE DRIVING MACHINE.**

BMW, MUNICH, GERMANY

# Spider and Fly Play Cat and Mouse

*"Come into my parlor," said the spider to the fly. The fly did—and had an excellent meal*

**by William G. Eberhard**

The spider and the fly—the bumbling, defenseless victim pitted in a hopeless struggle against a stealthy, overpowering foe. This popular piece of folklore is indeed an accurate picture of the relationship between many spiders and their insect prey. Nevertheless, spiders and insects have coexisted for more than 250 million years, with spiders constantly evolving to be more effective predators, and insects evolving defenses against them. Not surprisingly, with that much time and the large numbers of species involved, some unusual and complicated relationships have arisen. Recent research has uncovered a few of them.

Consider, for example, the case of the fly on the silken trapeze. When most spiders move about, they lay nonsticky trail threads behind them as safety lines. As a result, foliage where spiders have been active acquires a number of loosely strung threads, which accumulate until broken by strong winds or rain. Observing such a site at night, one can see that many of these deserted lines have tiny insects clinging to them. Most are flies of the gall gnat family (Cecidomyiidae), but representatives of at least seven other fly families, along with occasional small wasps and moths, also use the tiny trapezes. The insects' styles vary: some hold on securely with all six legs, some hang head down like bats or hang on the broken end of a thread, some hold on with their two front legs and spread the others wide, and some hold a line and copulate at the same time. Huge numbers of flies have been found hanging on spider lines. Enrique Lahmann and Claudia Zuñiga of the Universidad de Costa Rica found more than 500 flies on lines along the edge of a short stretch of trail and calculated that an average of about four flies were clinging to each three feet of spider thread; in just an acre of forest there must be times when tens or perhaps hundreds of thousands of flies are suspended on lines every night.

The significance of these acrobatics becomes clear with the realization that as perches the silk threads are nearly ideal defensive sites. There the flies can rest and avoid contact with twigs and leaves on which predators such as ants and wandering spiders prowl. If a spider does come out on a line, it gives a resting fly ample, though inadvertent, warning by vibrating the line, and the fly leaves. Many flies have even developed a special defensive behavior associated with the lines. When disturbed, they buzz their wings in short bursts; this causes the line to swing back and forth, and presumably makes them more difficult targets for potential predators.

Thus a number of flies have developed a defense against spiders by utilizing the spiders' own discarded silk. How flies can distinguish safe, nonsticky trail lines from the sticky threads in webs is not known. I have seen flies perching on the nonsticky support lines right at the edges of occupied webs; somehow they avoided getting entan-

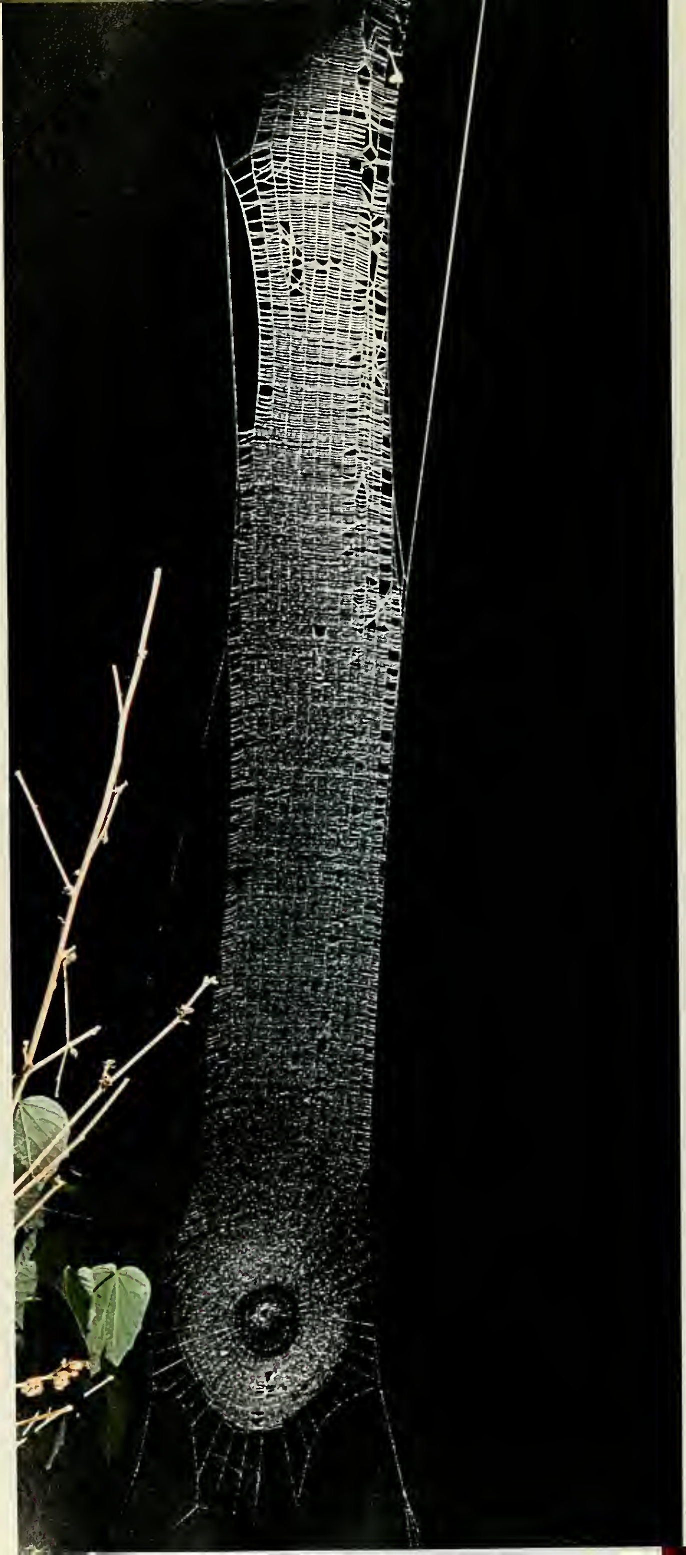
*An orb-weaving spider prepares to eat an enshrouded moth. Such webs are not well designed for catching moths, because a moth's detachable scales often stick to the web while the moth falls free.*

S.J. Krasemann; Peter Arnold

gled in the sticky central portion only a few inches away. A mistake could mean quick death, so the flies must be able to consistently make the correct choice or the silken trapeze habit would not have evolved.

Flies are not the only insects that have found protection by lodging with spiders. Mike Robinson of the Smithsonian Tropical Research Institute found that in New Guinea pyralid moths rest by day on nonsticky lines in the webs of the giant wood spider, *Nephila maculata.* This huge orb weaver, large enough to be roasted and eaten by New Guineans, builds large webs of very strong silk. There are instances of birds being trapped for hours in these webs, and experienced birds carefully avoid known web locations. Moths resting on such webs thus probably gain additional protection against insectivorous birds that will not risk predatory forays so close to the dangerous spider web.

Some insects have gone a stage further in their relationships with spiders and have become active food robbers. For instance, some species of the dance fly family, Empididae, hover slowly near orb webs along the edges of tropical streams and carefully land on small insects that have become entangled in webs but that are too tiny to draw the spider's attention. Recently, Randy Thornhill of the University of New Mexico has found that another group of insects—the scorpion flies, or Mecoptera—also make a habit of landing in the webs of spiders to steal prey trapped there. Large insects, scorpion flies cannot go unnoticed by the spider being robbed. Instead, they regurgitate a special liquid that serves a dual purpose: it repels the spider when it comes close to investigate, and permits the scorpion fly to disentangle itself from the sticky glue on the web's threads. This technique is dangerous, however, since spider attacks sometimes succeed, and Thornhill estimates that one of the major causes of scorpion fly mortality is predation by web-building spiders.



*Ladder webs are ideal for catching moths. A moth flying into the upper part of the web would be stripped of so many scales as it tumbled downward that it would eventually become trapped near the bottom.*

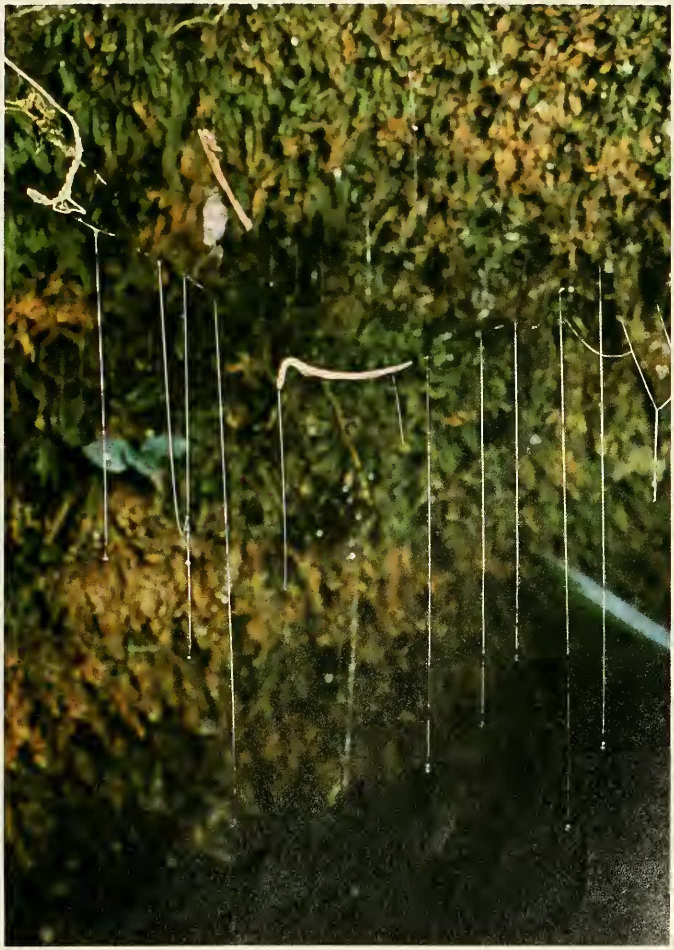
Mark Stowe

Other groups of flies have evolved even more effective tactics. One species of the family Chloropidae can be found during the day resting near an orb weaver that hides off its web in a curled leaf. When prey lands in the web, the spider rushes out, bites it and wraps it in silk, then carries it back to its retreat to feed in relative safety. But as soon as the spider returns with such a food bundle, the flies begin to edge in closer and closer. Their stealthy, hesitant movements remind one of the childhood game "red light, green light." When they get close to their goal, each fly unfolds a long sucking proboscis, and sticks it gently into the prey. After a minute or two of sucking, the fly walks away with its abdomen bloated, leaving the spider with its diminished meal.

This kind of robbery is brought to perfection by some other flies related to fruit flies. These, which were studied by Robinson, live with large orb weavers that sit at the center of their webs during the day. Some flies wait on the web, and others actually sit right on the dorsal part of the spider's body where the spider cannot brush them off. These flies do not have piercing mouthparts, but feed by taking advantage of the spider's method of eating (no solid food is swallowed; instead digestive juices are poured into the prey, and when its tissues have been broken down, the nutrient-rich broth is sucked up). The flies wait until the prey has been partially digested, then dart down off the spider's back, suck up a quick meal, and climb back on again. An Australian species of this group has become so closely adapted to the spider that in addition to robbing its host, the fly cleans it after its meals, carefully mopping off the spider's mouth and fangs and throwing in the extra service of cleaning around its anus after it defecates.

Moths are not outdone by flies when it comes to odd and specialized relationships with spiders. Robinson has found moth caterpillars living inside the giant colonies of the social cobweb spider, *Anelosimus eximus*. The colonial webs of this species sometimes reach several cubic yards, the size of an average room, and they persist for many years in favorable locations. The pyralid caterpillars living in the web are never very numerous, but they move about untroubled by the spiders, which stage devastating mass attacks on any other moving objects. The caterpillars live entirely on the undigested hard parts of the spiders' prey. Since the spiders do not have chewing mouthparts, they cannot cut up such cuticular material, but the moth larvae can, and their role is essentially that of scavengers. In an experimentally contrived situation, one caterpillar did attack a live insect before the spiders detected its presence, but this may not happen in nature.

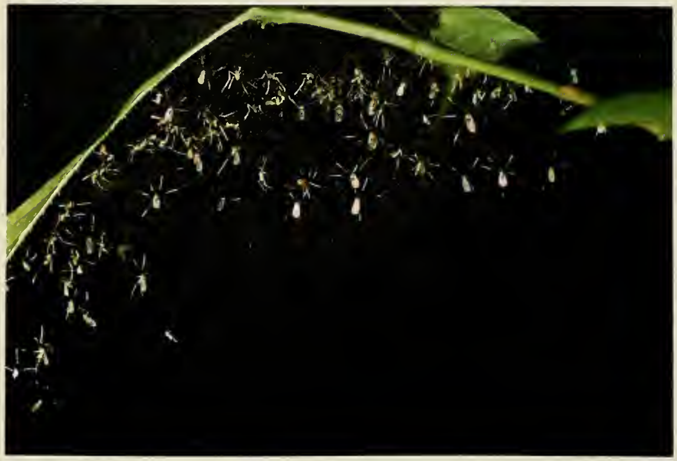
Perhaps the ultimate in role switching is displayed by flies that make webs themselves. These are actually larvae of the fungus gnat family, Mycetophilidae, and they spin webs consisting of numerous sticky lines hanging from a few nonsticky horizontal threads where the larvae crawl. These sticky curtains serve to trap tiny flying insects, which are then reeled in and eaten by the larvae. In one cave-dwelling species from New Zealand the larvae produce light, thus luring the prey to its death. These webs are inferior to spider webs because the sticky lines swing free and easily tangle together, even in a gentle breeze, but the larvae are very common in quiet, protected sites in the South American jungle where they are apparently fully competitive with spiders.



William G. Eberhard

*Spiders are not alone in using webs to capture prey. Here a fungus gnat larva produces a sticky line for its web; each line is tipped with an adhesive ball. When prey gets stuck, it is reeled in and eaten.*

William G. Eberhard



*A mob of flies rests on the nonsticky web of a comb-footed spider. Whenever the spider comes near, the flies take to the air, hover until the spider retreats, then return to their resting spots.*

These descriptions of how their intended prey turn the tables on them make the spiders seem almost inept. But spiders are a large, successful group, and as might be expected, they have evolved a few tricks of their own for the insects. Since I am a spider enthusiast, I cannot end this article without mentioning some of these.

One of the strangest came to light only recently. It involves the trapeze flies and an elongate spider that can perform the feat of curling and uncurling its abdomen like a spring. In the jungles of eastern Colombia these spiders build strange webs consisting of only a few long, nonsticky lines strung between leaves and twigs without any apparent organization. Such a web would seem to be useless for entangling insects; nevertheless it does help the spider capture its prey. It functions, not as a trap, but as a landing site for trapeze flies. When a fly alights on a line, the spider begins to move slowly and stealthily toward it, taking up to five minutes to move only three inches. When it finally nears the unsuspecting fly, the spider gently waves its front legs, like a blind person tapping with a cane. One touch is enough to reveal the prey's location; the spider slowly turns 180°, pulls out a sticky line with its hind legs, and with the only quick movement of the entire attack, suddenly loops the line over its victim.

Moths are also common spider prey, but they are difficult for web spiders to catch. This is because moths are covered with detachable scales, and when they hit a sticky web, some of the scales stick to the web while the moth falls free. Two kinds of spiders, one in New Guinea and the other in the Americas, have independently developed similar, bizarre webs that are probably adaptations to overcome this defense of the moths. In both cases the webs are extremely elongate and perfectly vertical and have thus been christened "ladder webs." A moth striking the upper part of a ladder web has so far to fall that it is stripped of scales and firmly entangled before it can reach the bottom and free itself.

Another spider group has gone in for even more sophisticated moth-catching tactics. These species' webs have become reduced rather than extended, and consist of only a single short line from which a large sticky ball is suspended. These "bolas spiders" hold the line with one front leg and swing the ball at passing insects. This seems an incredibly ineffective way to go about catching prey, but recent observations have confirmed what naturalists had long suspected—that the spiders do not passively wait for prey to chance by but actively attract them by using a substance apparently similar to one produced by virgin female moths to attract their mates.

The spider begins by choosing an exposed site and making a ball; then, swaying slightly in the weak nighttime breeze, it settles down to wait, holding the line. The spider's tension is suggested by the nearly constant twitching of its front legs. Alertness is essential, since the spider's sense of vision is very poor. Probably it senses approaching prey by the hum of wings. This charged scene may last for many minutes before a fluttering white speck appears in the moonlight, swinging back and forth in the air downwind of the spider. The moth approaches erratically, seemingly unable to keep its flight pattern steady in the gentle breeze. But after coming to within about three feet, it appears to sense that something is wrong and speeds away. More waiting by the spider follows, until another erratic approach begins. The moth hovers closer and closer, and the spider, finally alerted to its presence, cocks its leg back ready to swing. It starts several swings, but holds up as the moth swerves first closer, then farther away. Finally the moth slips off to the side and disappears, only to reappear moments later downwind and begin another approach. Again it comes close, and again the spider cocks its leg. Suddenly, too fast for the human eye to see, the spider swings, and the moth flutters helplessly at the end of the line. The spider descends, embraces its victim while administering a paralyzing bite, then slowly wraps it securely in silk.

These glimpses of spider–insect interactions are by no means the end of the story. Insects of several other orders are involved in complex relationships with spiders in their webs, and wherever one looks in depth at spiders and their potential prey, all is complexity. Nature has been much more creative than our simple stereotypes have led us to believe. This is especially true in the tropics where the diversity of organisms and the opportunity for specialization are great. For naturalists, the beauty of these seemingly endless variations on basic patterns is both a source of pleasure and an inspiration to further study. ☐

*Hanging from a support line, a bolas spider of the genus* Mastophora *dangles the weapon for which it is named. The sticky ball at the end of the line is swung at passing insects such as moths.*

# A Fish with Double Vision

*Native to the Galápagos Islands, this animal has a most unusual optical system*

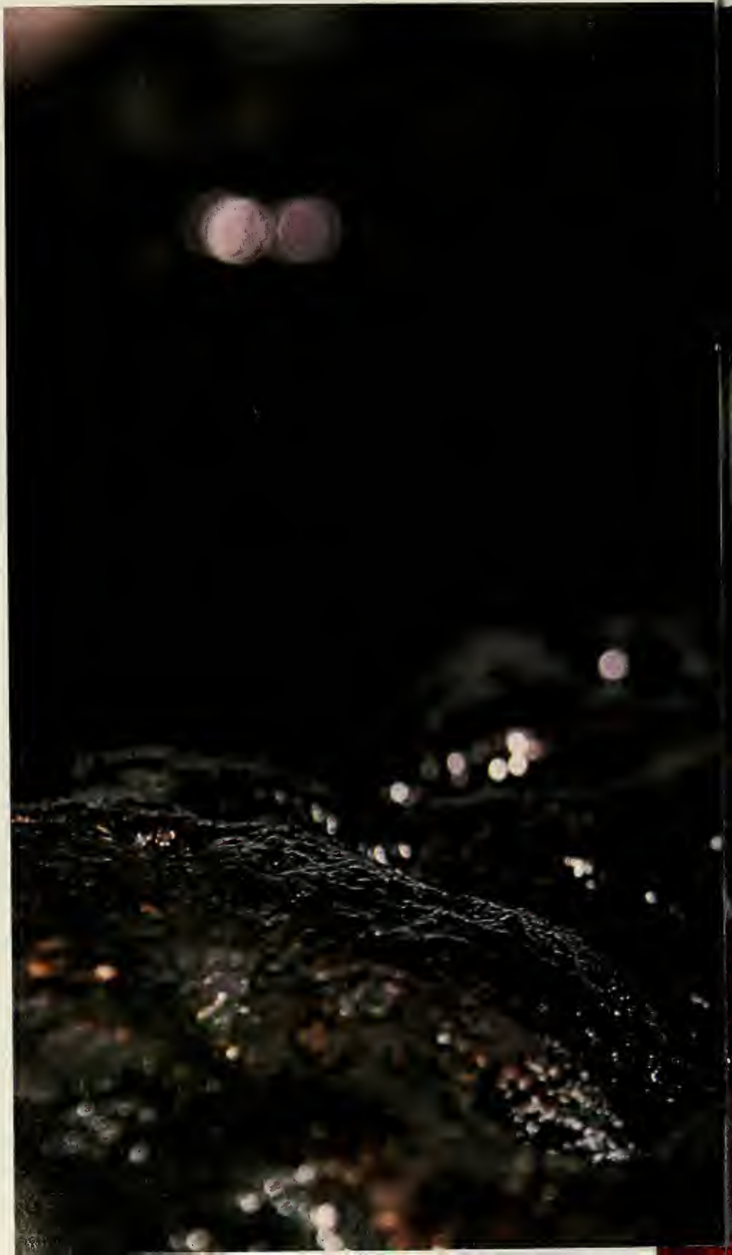
**Text and photographs by John K. Stevens and Katharine E. Parsons**

The Galápagos Islands, which lie about 650 miles off the coast of Ecuador, are probably best known as a place where Darwin made observations that helped him develop his theory of evolution. They are also famous for their gigantic land tortoises and unusual birds. In addition to these and many lesser-known animals, the islands have a small amphibious fish found nowhere else—*Dialommus fuscus*. This fish is probably unique in that its eyes have two absolutely flat corneal windows that form a prism and enable it to see sharply in both air and water.

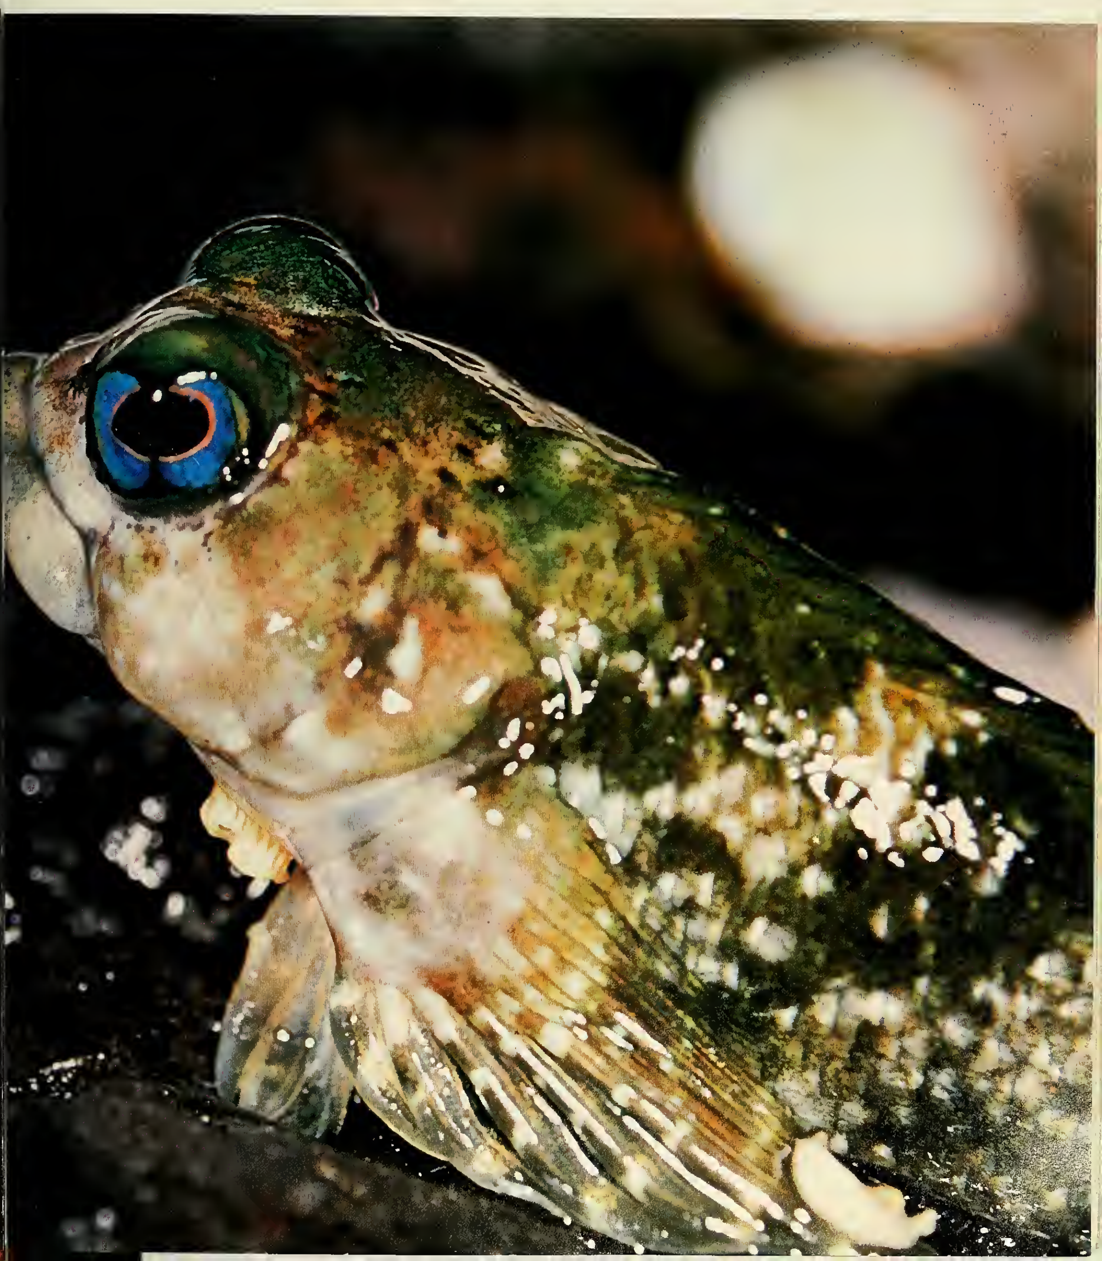
In order to study the fish and its optical system, we made a scientific trip in 1976 to Santa Cruz, the second largest of the Galápagos Islands, and set up a laboratory in the Charles Darwin Biological Station.

*D. fuscus* is approximately two to six inches long. Its location and activity determine its body color, which ranges from gold to black. Its eyes have a brilliant iris of blue, black, and red, and the two corneal faces of each eye are set at an angle of 110 degrees to each other. We found the fish most often in the tide pools along the rocky shores of this volcanic island. Since it lacks a swim bladder, the fish maintains its position in the water with its tail and fins, which it also uses to pull itself out of the water. In fact, *D. fuscus* spends up to 50 percent of its time out of the water, coiled up on the lava rocks waiting to jump either at food or back into the tide pools to escape its predators. It moves quickly and is difficult to catch, which may be one reason it has not been widely studied in the past.

*D. fuscus* is an aggressive and voracious feeder. In the laboratory, it would hop on a rock and literally tear food from our fingers. In the field, however, it curls into the small crevices of the lava rock and feeds opportunistically off the tiny shrimp and other crustaceans that the surf carries in. Despite its small size, it can often be located by the pecking noises it makes as it snaps at its prey against the



*This specimen of* Dialommus fuscus *has just climbed out of the water. In a few minutes its body will turn black, matching the lava rock on which it is sitting. Its blue, prismatic eyes, with their clear vertical division, will also turn black on exposure to the bright light.*

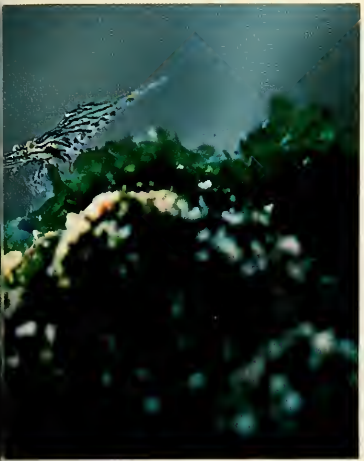


*The prismatic effect seems to have disappeared from the eyes of this fish, which has just jumped underwater. Its eyes will soon change color, adapting to the diminished light.*

rock. With its extremely mobile head and body it would often "fish" for food stranded in tiny pools of water only fractions of an inch in diameter. To the casual observer, the fish appears to be eating the rock itself. Because of this characteristic feeding behavior, the native name for *Dialommus* is *chupa piedra*, "rock eater."

To leave a tide pool, the fish first "hyperventilates," that is, takes several deep breaths at the water's edge, curls its tail around, and then propels itself out of the water like a rocket. The pelvic and pectoral fins work together with the tail to move the fish's body rapidly over the rocks. It leaps into the air to escape terrestrial predators, such as lava herons and carnivorous crabs, or surfs across a tidal pool to another rock. We often observed *D. fuscus* out of the water for twenty minutes or more, and during these terrestrial sojourns it kept its gills clamped shut, much as we keep our mouths closed when holding our breath underwater.

During the course of our investigation we heard from a nature guide that *D. fuscus* might inhabit other islands besides Santa Cruz, so we persuaded three fishermen (others refused because of the pervading rough seas) to



*Tiny shrimp, sometimes of microscopic length, wash up in tide pools along the coast and become food for* Dialommus fuscus.

*The habit of pecking at these shrimp and other crustaceans on the rocks has caused the native population to dub the fish the rock eater.*

take us to Hood Island and Floreana Island. On Hood, we found the fish in only one location, on the island's south side by a blowhole (a hole in the rocky roof of a sea cave through which incoming waves force upward a powerful jet of water). We were astonished to find the fish in small pools on ledges well above the tide line—pools they could only have reached by being propelled up through the blowhole under several hundred pounds of water pressure.

On Floreana, which has sandy beaches and where there is less surf action than on Hood, we found only a few of the fish in one of the bays. Our three skilled fishermen were able to catch the fish with their hats and their bare hands while we struggled with nets. For some strange reason, *Dialommus* did not seem as amphibious or as hardy on Floreana (two died after an hour in our collection bucket) as the fish we studied on the rockier islands of Hood and Santa Cruz.

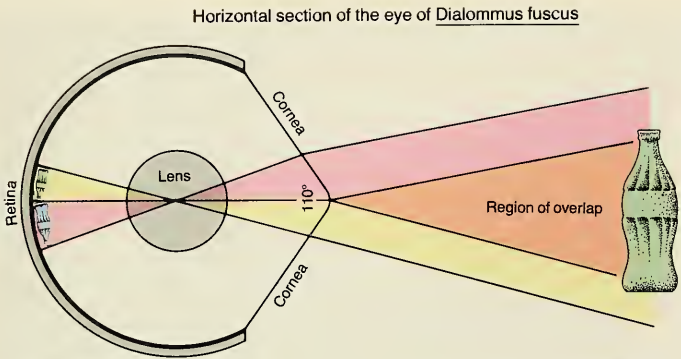
Its chameleonlike characteristics enable *D. fuscus* to blend into the background, whether under or above water. On Hood Island, for example, when in the water, the fish were a deep golden color, like the algae peculiar to the tide pools there; those on Santa Cruz, by contrast, were green, brown, and tan, blending with the tide pools on that island. When the fish left the water, however, they changed color within a matter of minutes, turning black to match the lava rocks. We do not know what mechanism accounts for these color changes. They may be triggered by exposure to light or to changing levels of oxygen or carbon dioxide in the fish's blood.

Despite these intriguing characteristics, we focused our scientific investigation on trying to understand and reconstruct the optical system of *D. fuscus*. First, in the laboratory, we examined an eye in vivo with a conventional ophthalmoscope, which made direct viewing of the retina possible. We then withdrew minute samples of fluid from the anterior and posterior chambers of the eye, and measured the refractive indices of the aqueous and the vitreous humors—the fluid and the jellylike substances, respectively, in the chambers.

To measure the focal length of the fish's eye, we used a helium-neon laser. First, the lens was removed from the eye and placed in a solution with a known index of refraction. The laser was then shined through both the solution and the lens, which focused the laser's parallel rays to a single point. The distance from the center of the lens to this point was recorded photographically and, as expected, corresponded to the focal length of the lens.

Finally, we quick-froze a series of whole eyes with freon and cut them into 40-micron-thick serial sections. Photographs of these serial sections were used later to reconstruct the entire eye on a computer. When all of this information was put together, it became possible to model the optical system of the entire eye of *Dialommus*.

During our study, we found that the refractive index of the fluids in the fish's eye approximated that of sea water. Consequently, it was clear—as others had suggested before—that *D. fuscus* had evolved an equivalent of a



Joe Le Monnier

*The combination of the fish's prismatic cornea and the index of refraction of 1.0 in the air leads to a double image of the world when out of the water. This double view, or "binocular" of 20° to 30° overlap, may contribute to depth perception or may simply be an evolutionary aberration.*

*The chameleonlike ability to blend with its surroundings makes the fish almost unrecognizable, above, and barely discernible, right.*

face mask that made it possible for the fish to see clearly both in the air and underwater. Just as we need an air space in front of our eyes to see underwater, so this fish needs a "mask" of "sea water" to focus in the air.

Our model, however, predicted one interesting difference between a face mask and this fish's eye. Since the eye's corneal windows consist of two flat faces similar to a glass prism, set at an angle of 110 degrees, and since the fluids inside the eye match the refractive index of water, the eye should produce a normal image underwater. But our analysis shows that when the fish comes above water to feed and looks directly at an object (through the center of the "prism"), there should be a 20- to a 30-degree field over which it sees double, perceiving every object twice with each eye. This double view may simply be an aberration—the evolutionary price *D. fuscus* has paid for its aerial vision. On the other hand, it may be a mechanism that makes depth perception possible. Since *D. fuscus* sees things twice above water, it can make use of visual disparity cues, which humans obtain from two eyes, with only one eye. If true, this possibility might represent a unique evolutionary development that should be explored in greater detail.

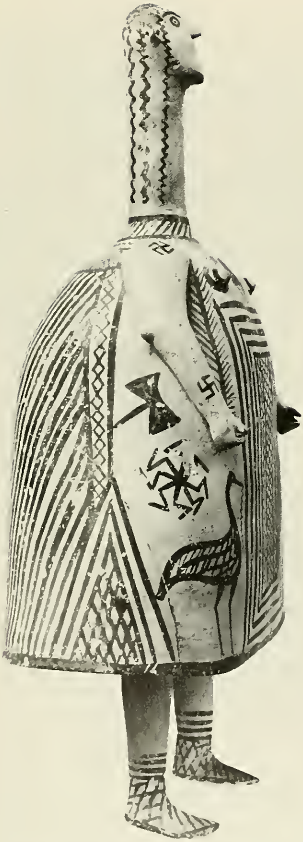
We later confirmed empirically with our photographs of the fish that a double image probably does occur when the fish is out of the water. Photographs of the fish's eye taken at a sharp angle showed the iris twice, demonstrating that the cornea is indeed a prism when above the water. Consistent with our model, however, no double iris showed up in any of our underwater photographs.

We were most surprised to discover that *Dialommus* had also evolved, in the anterior chamber of its eye, a photopigment that changes in optical density on exposure to bright light. Normally the iris is a brilliant blue, but when the fish is exposed to bright sunlight, the iris and the fluid in the anterior chamber of its eye turn black like the rest of its body. Since the fish lacks a constricting iris like that in humans, this change presumably protects the fish's retina from the brilliant equatorial sun. Thus, it appears that *D. fuscus* not only has special vision but may also have anticipated by several million years the "variable density sunglasses" now available to humans. ☐

# Origin of the Swastika

*Ceremonies in India have shed new light on an ancient symbol*

**by Stanley A. Freed and Ruth S. Freed**



*Many theories of the origin of the swastika are based on its association with other symbols of recognized meaning, such as this clay female figure from a seventh-century B.C. Boeotian grave.*

M. Chuzeville, Musée du Louvre

The swastika is humanity's oldest, most widespread symbol of any complexity. The name is derived from a Sanskrit word that means "object of well-being." Originating some 6,000 years ago in the Middle East, the symbol had spread over Europe and parts of Asia by the early centuries of the Christian Era. In recent times, the Third Reich, exploiting the symbol's mysterious magical power, impressed the swastika into the consciousness of the world. Hitler's early biographer, Konrad Heiden, described the impact of its first public display in prewar Germany: "In 1921, Hitler's new red banner with a black swastika in a white disk was unfurled in the open for the first time. The effect was so inflammatory that Hitler himself was surprised and pleased. [It] gave Hitler one of his mightiest magical weapons. . . . An uncanny power emanated from the mysterious sign."

Because of the association of the swastika with Nazism, the nations most affected by the Second World War regard it as a symbol of barbarity. But apart from this recent, menacing aspect, which covers only one percent of its history, the swastika is a powerful sign of good luck. This quality, its magical aura, and its symbolism have roots in the most ancient civilizations of Mesopotamia and Iran. In India, where it is widely used in Hindu ceremonial and as a decorative motif, the swastika combines astronomical and religious symbolism. This combination provides our best clue to its original meaning, for a continuous religious tradition can be traced from modern Hinduism to the religion of the Harappan civilization of the Indus Valley, which has been dated to the third millennium B.C.

The trail begins with the earliest recorded occurrences of the swastika at Samarra in central Mesopotamia and at Susa in western Iran, where clear swastikas appear on pottery from about 4000 B.C. About 3000 B.C., the swastika was depicted on pottery from Troy in northwestern Asia Minor and, somewhat later, on seals from the Harappan civilization. By the beginning of the Christian Era, the swastika was well established in an area from India through western Asia into Europe. This zone of primary diffusion largely coincides with the area settled by speakers of Indo-European languages. Although widespread in the Middle East and Asia Minor, it was notably absent in nearby Egypt, except on imported goods such as Greek pottery, and was generally unknown in the rest of Africa.

A later diffusion of the swastika took place in central and eastern Asia. Buddhism adopted the swastika from Hinduism, and as Buddhism spread from India into Tibet, China, and Japan, the swastika traveled with it, retaining its symbolic meaning of good luck.

*A swastika decorates this Hindu temple in New Delhi. Perhaps the best clues to the swastika's original meaning lie in India, where it has been used in daily and ceremonial life since antiquity.*

Rajesh B

*The true, hooked-cross swastika was generally absent from the New World before its introduction by Europeans. At right is an exception, one of several copper swastikas unearthed from one of the 2,000-year-old Hopewell mounds in Ohio. Because of its isolated occurrence, this find may be interpreted as a case of independent invention of a shape whose symbolism, if any, would have been unrelated to the swastika of the Old World.*

Field Museum of Natural History, Chicago

The most vexing distributional problem regarding the swastika is the question of its occurrence in the New World in pre-Columbian times. Almost all of the pre-Columbian designs alleged to be swastikas, such as the cross in a circle, which is common on shell ornaments, and the spirals that often decorate pottery, bear only a modest resemblance to the typical hooked-cross swastika of the Old World. The elimination of such dubious examples all but removes the swastika from the pre-Columbian New World except for one case, the 2,000-year-old Hopewell mounds in Ohio. There, in the early 1890s, archeologists unearthed a cache of copper objects that still constitutes one of the most remarkable finds in North America. Included were several true swastikas, whose existence is puzzling, for there are no comparable objects from other sites in adjacent regions. Ordinarily, artistic motifs diffuse rather widely—for example, the cross in a circle occurs in both the Old and New Worlds. In post-Columbian times, Europeans brought the swastika to the New World, and American Indians have occasionally used it as a design element.

Scholars have proposed a considerable number of theories for the symbolic meaning of the swastika: that it represents the sun, moon, the yearly rotation of Ursa Major, cardinal points, eternity, Zeus, Baal, fire, several Hindu deities (among them Agni, Indra, Vishnu, and Ganesh), light, forked lightning, water, the union of the sexes, fertility, and a fire-making apparatus known as the fire drill. Ranging from reasonable to far-fetched, these theories rely on the proximity of the swastika in various contexts to symbols of recognized meaning or on the reputed natural functioning of the human mind. John, Prince Loewenstein, for example, in an article published in 1941, wrote: "The *swastika*, which from the earliest times was so closely associated with woman, must . . . have been a fecundity symbol." He cites such evidence as the presence of the swastika on female face urns from Troy dating to about 3000 B.C. and on objects associated with women, such as spindle whorls and loom weights.

A common proposition is that the swastika represents the sun. In 1894, Count Goblet d'Alviella, following several other authors, argued the theory largely on the basis of the association of the swastika and symbols, images, and deities of the sun. The frontispiece of his book *The Migration of Symbols* shows Apollo, clearly represented as a sun god, with a swastika on his breast.

Anthropologist Zelia Nuttall advanced a theory based chiefly on "ideas which would naturally suggest themselves to the mind of the primitive observer." Such a person, observing the yearly rotation of Ursa Major around the pole star and concentrating upon its image at four equidistant positions, would perceive the form of a swastika. Her own experience illustrates the mental processes involved:

> In a flash of mental vision I perceived a quadrupled image of the entire constellation, standing out in scintillating brilliancy from the intense darkness of the wintry sky . . . it bore the semblance of a symmetrical swastika of giant proportions. . . . I left my window, on that memorable night, with a growing perception of the deep and powerful influence the prolonged observation of Polaris and the circumpolar constellations would naturally have exerted upon the mind of primitive man.

Such interpretations are unconvincing principally because of the lack of a clear connection between the form of the swastika and its alleged symbolic meaning. The circular sun is not readily apparent in the angular swastika; the connection between the swastika and, for example, an elephant-headed deity (Ganesh) or the union of the sexes is even more obscure. Moreover, the insight that comes from observing how people actively use a symbol is lost when interpretations are based solely on archeological artifacts that represent dead cultures. The best context in which to search for the symbolic meaning of the swastika is in a living society where the symbol has from ancient times been a routine feature of ceremonial and daily life. India provides such a setting.

Swastikas are in constant use in the north Indian village where we have lived for extended periods. They are prominent in ritual life, especially in ceremonies that mark a beginning, such as births and marriages. A priest officiating at such rituals sometimes includes a swastika in the symbolic design, drawn in colored powders on the ground, that serves as an altar for the fire rite. In ceremonies of birth, marriage, and at festivals, women often draw swastikas on pots, the ground, and walls. When a symbol representing a festival is removed after the conclusion of the festival, women

sometimes draw a swastika in its place so that no evil may enter the empty space. We observed the swastikas in such rituals but did not always pay particular attention to them, since they were ubiquitous. The villagers told us that they drew swastikas because they were auspicious, and we could not elicit more specific information.

One day we were watching a ceremony known as *barat lena* (reception of the wedding party), one of the series of rituals that constitutes a wedding. At *barat lena*, the groom is welcomed by men of the bride's family. Since we had often seen similar rituals, we expected to see nothing particularly new, but this time we had a stroke of luck. A large brass tray containing sacred paraphernalia and symbols had been prepared for the ceremony; on it was a faint swastika drawn in turmeric. At each of the nine points that, when connected, defined its form (the center, vertices of the angles, and the end points of the arms), a pile of rice had been placed.

We were forced to see with fresh eyes what we had looked at many times before. Like most people who have written about the swastika, we had been in the habit of looking at its arms. The prominent rice piles and faint arms directed our attention to the nine points arranged in a three-by-three square as the essential feature of the swastika, a shift of focus that led us to a new interpretation of its symbolic meaning.

*Throughout much of the world today, the swastika retains its value as a symbol of good luck. It was spread into Tibet, China, and Japan, left, in association with Buddhism, which adopted the symbol from Hinduism.*

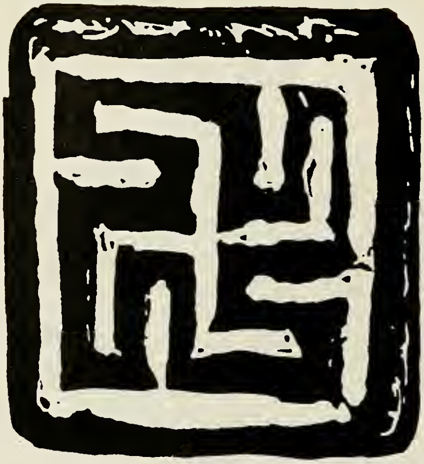
e Bartruff

In Hinduism, there are nine supernatural beings known as the *graha*. They are the five planets visible to the naked eye (Mercury, Venus, Mars, Jupiter, and Saturn), the sun, and the moon—all seven considered to be gods—and the ascending and descending nodes of the moon, conceived of as demons that pursue the sun and moon and cause eclipses. (The nodes are the points on its orbit when the moon lies in the same plane as the sun and the earth, the only times that eclipses can take place.) Traditional Hindu astronomy designates the *graha* as planets; the gods and demons immanent in the *graha* are called the planetary deities.

In Hindu samskaras (orthodox ceremonies), the *graha* are usually represented by nine squares in a three-by-three pattern, each one often bearing the symbol of a specific deity, or more simply by nine dots. The central square represents the sun, the creating principle, around which are arranged the other planetary deities that, together with the sun, represent the entire universe. Further indications that drawings of the *graha* are intended to encompass creation and the universe are the one or more short, projecting lines that are often drawn at the edge of the three-by-three pattern of squares. Such lines stand for the multitude of deities not specifically represented in the drawing of the *graha*.

In the context of a Hindu wedding ceremony, where the nine planetary gods are so prominent, the connection between the swastika and the planetary deities becomes obvious. The symbolism of the swastika is contained in its nine points, which represent the planetary deities; the lines are a dramatic way of connecting the points to make them more visible. The swastika can be drawn more quickly than a three-by-three square, and there is a feeling of motion and excitement about it. The swastika may have been used as a substitute for squares or other representations of the planetary gods so long ago that its original meaning has been forgotten. On one level, the swastika represents the planetary deities; at a deeper, or more general, level, it symbolizes the power of creation and the universe, just as does the three-by-three pattern of squares that also represents the *graha*.

The connection of the swastika and the planetary gods is often seen in designs drawn to serve as altars for fire ceremonies. We photographed one altar displaying both a large swastika and a small drawing of the nine squares. This double appeal to the *graha* was justified in this case, for the ceremony was intended to protect a male infant and his family from the harmful effects of a malevolent astrological sign. The baby had been born under the sign of the Mula Nakshatra. There are twenty-seven nakshatras, or lunar mansions, conspicuous stars or groups of stars that lie near the moon's path as it revolves around the earth. Recognized and named in ancient times, they are believed to affect the



*The swastika appears on seals from the Harappan civilization of the Indus Valley, which dates from about 2300 to 1700 B.C. Hinduism is a living religion with roots in this ancient culture.*

fate of individuals for better or for worse. Rural north Indians believe that the Mula Nakshatra has the most dangerous influence. A male child born under that sign either dies or, if he lives, brings ruin to his family.

Invoking the powerful planetary gods as protection from a malign nakshatra was doubly appropriate because of a connection between the *graha* and the nakshatras. In Hindu mythology, the lunar mansions were the daughters of Daksha (Ritual-Skill), who gave them to the moon as wives. The first offspring of this union were four of the *graha*: Mercury, Venus, Mars, and Jupiter. The four small circles in the angles of the intersecting arms of the swastika drawn for the Mula Nakshatra ceremony may represent these four planets born from the union of the moon and four nakshatras; this added symbolic element would be appropriate in a ceremony for a nakshatra.

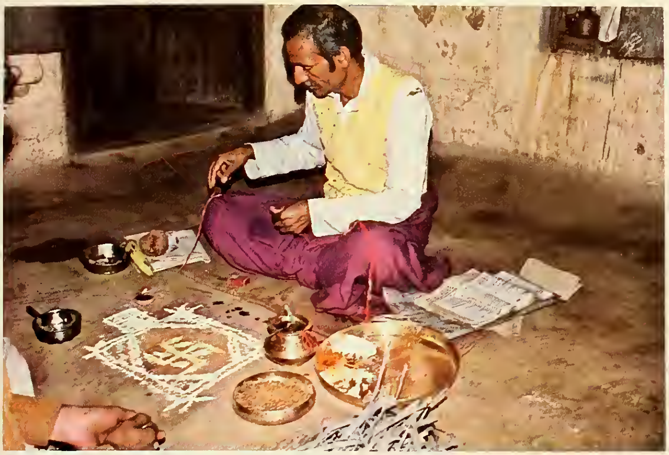
To use the identification of the swastika with the *graha* based upon ceremonies observed in 1978 as grounds for a theory of the origins of the symbol assumes some continuity of Indian religious tradition from ancient times to the present. Such an assumption is by no means unjustified. Links between the Harappan civilization of the Indus Valley, which dates from the third millennium B.C., and modern Hinduism appear well established. Stuart Piggott, in *Prehistoric India*, concluded that Harappan religion was "essentially Indian from the start." The swastika appears on Harappan seals, as does the grid, another symbol that depicts nine points and may also have represented the planetary deities.

The relationship of the swastika and the planetary gods fits the history and distribution of the symbol rather well. The necessary astronomical knowledge existed at the swastika's apparent place of origin. The Mesopotamians had identified the five planets, and they had also learned to "half predict eclipses," as American anthropologist Alfred Kroeber phrased it. Thus, they would have known about the ascending and descending nodes of the moon. Moreover, the Mesopotamians identified the planets with gods.

When the week was invented in western Asia, the names of the Babylonian planetary deities were used to designate the days. As the week diffused over the Old World, the peoples who accepted it, such as the Greeks, Romans, Germans, and Indians, renamed the days after their own deities. The connection of heavenly body–god–weekday from India to Europe coincides with the area most anciently identified with the swastika, strengthening its interpretation as a symbol of the planetary gods. Its comparative absence in other areas of the world also is in accord with this interpretation. In Egypt, for example, where the only planetary deity was the sun god, the original symbolism of the swastika would have had little meaning. The swastika was probably spread as much by the migration of the Indo-European tribes as by diffusion; in any case, it is more closely identified with speakers of Indo-European languages than with other populations and has found its greatest use among them.

Consideration of the swastika as a symbol of the planetary deities would simplify some matters that have occupied archeologists and historians. The problem of alternative forms of the swastika could be reappraised. Symbols that lack nine clearly defined points in a three-by-three pattern are probably in most cases not swastikas. A reanalysis of such forms would bear on the problem of the diffusion of the swastika, especially its presence in the New World. The various spirals and crosses in circles that pass for swastikas in the New World probably had nothing to do with the hooked cross of the Old World. The copper swastikas from the Hopewell find, however, remain mysterious. Whether the Hopewell swastikas are evidence of Old World influence or were independently invented in the New World, it is hard to explain why the design was not further diffused.

In recent times, there appear to have been two peak periods of scholarly interest in the swastika: the first about the beginning of the twentieth century; the second during the period of the Third Reich in Germany. At present, analysis of symbols is one of the noteworthy interests in anthropology. Yet one of the most famous—or infamous—symbols of all has been largely ignored. Because of the many archeological investigations in the Old and New Worlds since the Second World War, this would seem to be a good time to advance our understanding of this mysterious symbol, which recalls the deities and demons that guided human destiny at the dawn of civilization. Its principal heirs, the Indo-European speakers, still respond to its mystical power. □



Stanley A. Freed

*In specific instances, the details of Hindu ceremonial suggest that the swastika symbolizes ancient planetary gods. # Indian Fires of Spring

*Hunters and gatherers of the Canadian boreal forest shaped their habitat with fire*

**by Henry T. Lewis**

Following years of research—and sometimes acrimonious argument—environmental agencies across North America have begun implementing programs of prescribed burning. They are setting low-intensity, controlled fires to change or maintain natural environments. In addition, many fires started by lightning are now allowed to burn in high-altitude wilderness areas where there are few human habitations or timber resources. Such forestry management burning is not new. It has been carried out on a small scale for several decades within certain restricted habitat types, such as the longleaf pine forests of southwestern Georgia. But the widespread change in official attitude marks one of the more significant developments of this century in the forestry and range management sciences.

We are just beginning to appreciate the complexities and sophistication of this age-old custom. Anthropologists have noted habitat burning by nearly all known populations of North American Indians. Similar reports from Latin America, Africa, Eurasia, and Australia indicate the near universality of these practices among other hunters and gatherers, as well as among pastoralists. Unfortunately, the opportunities for direct observation have all but disappeared, except for isolated portions of Africa, Southeast Asia, and Australia where burning takes place surreptitiously or in the face of ineffective law enforcement.

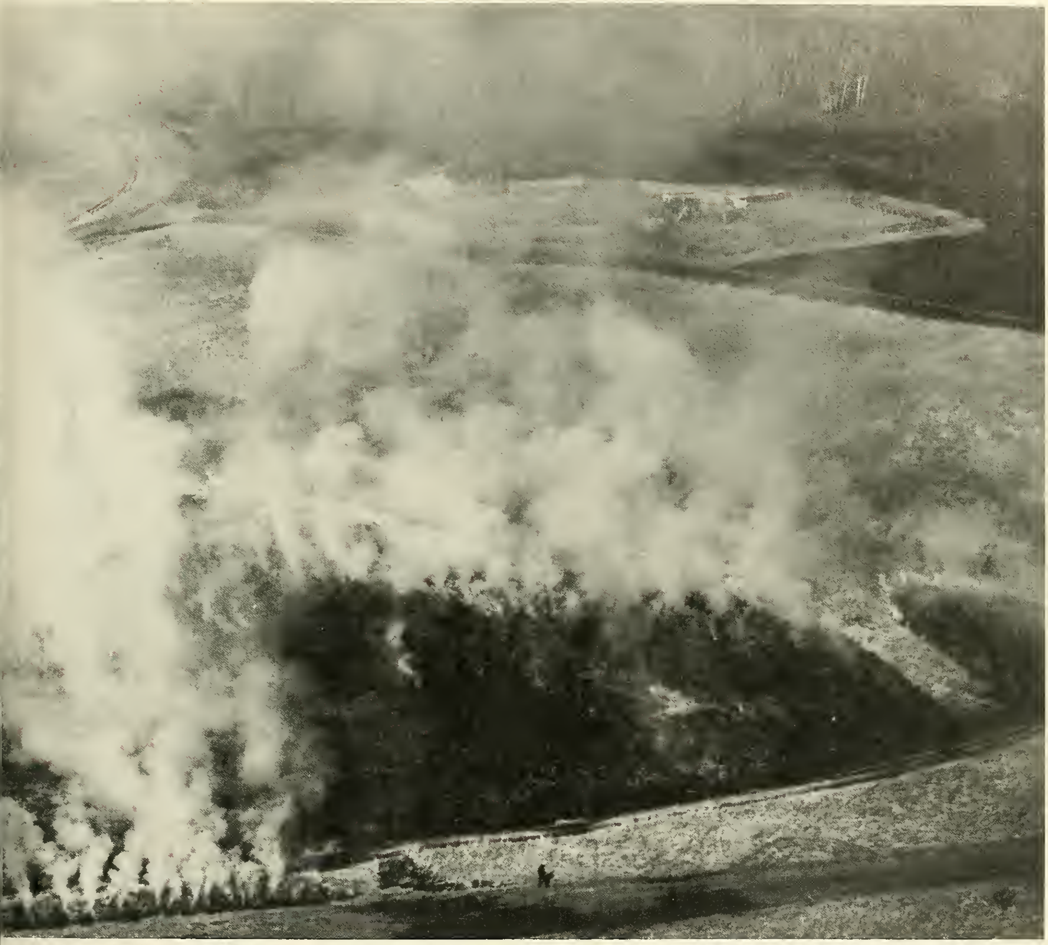
The Indians of Canada's northern boreal forests, or taiga, are among those who until recently employed fire to control and alter selected habitats. In Alberta's remote northern section, Slavey, Beaver, Cree, Chipewyan, and Métis (so-called half-breeds) maintained the traditional practices until the completion of the Mackenzie Highway in 1949, when oil field developments brought an end to the region's isolation. With the intrusion of roads and communication systems, environmental agencies were finally able to enforce existing fire laws. Today, just when provincial and national agencies are discovering the advantages of controlled burning, only the oldest Indians, those over sixty, can recount their own folk science of fire. (Members of the younger generation may remember occasional, secretive firing of isolated meadows, but they are usually poor or unwilling informants because they have been much influenced by public attitudes about fire.) A Beaver Indian woman reminisces:

> Why the bush is so thick is because they stop burning; the Indians stopped burning. From about five miles from here you could see straight prairie right to Childs Lake and that timber. Did you ever see them prairies? My goodness, I even remember. It was really prairie, just prairie, you know; here and there you see little specks of woods, and if there were trees there, they were quite huge.

In northernmost Alberta, the largest grassland areas are the intermittent prairies of the lower Peace River basin, which range in size from thirty to more than one hundred square miles. Meadows of but a few to several hundred acres are scattered widely, and deep within the boreal forest, there are small clearings, or swales, in areas that remain waterlogged throughout spring, summer, and fall. The countryside is also broken by meandering strands of grassland associated with streams and more swampy water drainages. These boreal forest sloughs, all but impassable in the summer, are the favored habitat of beavers, moose, muskrats, snowshoe hares, voles, and mice.

To Canada's wheat growers, this region constitutes a last frontier where forestlands are still being cleared for highly mechanized cultivation. The original pioneer farmers, however, were not faced with vast, uninterrupted stands of forest. Those early settlers who arrived in the first quarter of this century with their hand tools and horse-drawn plows found extensive prairies and parklands that supported

Henry T Lewis



*John D'or Prairie, a grassland created by the Indians' traditional use of controlled burning, is still maintained by annual spring fires authorized by the Alberta Forest Service.*

untold numbers of woodland bison, the remnant populations of which are today found only in Wood Buffalo National Park. ("My father told me that long time back there were plenty of buffalo here, all the way to Cold Lake. We were Plains Cree, not like those bush people up north. Now it's all bush here too," complains a Cree Indian from Frog Lake in central Alberta.)

George M. Dawson, a naturalist and government surveyor, wrote in 1879:

> The origin of the prairies of the Peace River is sufficiently obvious. There can be no doubt that they have been produced and are maintained by fires. The country is naturally a wooded one, and where fires have not run for a few years, young trees begin rapidly to spring up. The fires are, of course, ultimately attributable to human agency, and it is probable that before the country was inhabited by the Indians it was everywhere densely forest-clad.

The High Level–Fort Vermilion prairie, an area of roughly one hundred square miles, was regularly burned each year. Smaller prairie-meadows, such as Tall Cree, John D'or Prairie, and those at Hay Lake and Bistcho Lake, were also fired, as were myriad small meadows, swales, and sloughs. Within the whole of northwestern Alberta, a region of some 26,000 square miles, an estimated 650 square miles was burned in any given year. Ironically, these fire-maintained prairies provided a measure of preadaptation for the pioneer farming that displaced Indians from some of their prime hunting lands.

Along with less dynamic conditions (climate, soil, exposure, topography, permafrost, availability of seed plants), fire serves to counteract the tendency toward forest uniformity. A mix of variably aged forest, brush, and grassland types provides for a greater number as well as a diversity of plants and animals. In setting fires according to an intended pattern, hunter-gatherers can reap these benefits and, at the same time, reduce the risks of natural

Henry T. Lewis

*A meadow has become lush three weeks following a spring fire, while unburned dead grass (foreground) inhibits new growth. With annual burning, the grassland area expands as trees on the periphery are affected.*

fires, whose frequency, intensity, extent, and effects are unpredictable.

In northern Alberta, Indian fires were characteristically set during the first week of spring. Such spring burning can maintain herbaceous plants at high levels of productivity year after year in selected sites, without disruptive effects. This is favorable for bison and other game animals, especially species that frequent the border areas separating forest, grassland, and water. In the boreal forest regions of northern Canada, these species include moose, elk, deer, bears, snowshoe hares, beavers, muskrats, and further along the food chain, a variety of dependent predators. Even caribou, which depend mainly on the lichens and mosses of mature forest stands, will at times forage in clearings or along sloughs and riverbanks.

Spring burning promotes early growth, an important advantage to hunting and gathering in a region with only sixty to eighty frost-free days a year. With its surface cleared and blackened, the frozen soil of a meadow is heated by the sun, and growth occurs two to three weeks earlier, and is lusher, than in unburned areas. In northern latitudes, where the natural recycling of nutrients is slow, fires also help "unlock" nutrients, increasing their availability to plants.

The practice of spring burning thus aided the northern hunter-gatherers in meeting their subsistence goals. Other reasons for burning meadows, whether close to campsites and settlements or farther removed on traplines and hunting grounds, were to reduce fire hazards, facilitate travel, improve berry patches, provide firewood (from fire-scarred trees and brush at the edges of meadows), and decrease populations of black flies and mosquitoes. Aesthetic and religious feelings were bound up with these practical considerations. "Windfalls—where there's all dead trees—those aren't good places," says a Slavey Indian. "Nothing lives there, nothing is any good. We set fire to those places in the spring. That way the fire makes the forest live again."

In controlling fires, the Indians made the same fundamental evaluations employed in forestry and range management today. Foremost was the rule of seasonality: fires were set in spring, occasionally autumn, never summer.

The conditions under which grass fires may be set during the early weeks of spring persist for only a few weeks or, in some years, for but a few days. By mid-April, forest openings are cleared of snow and the exposed grasses dry much more rapidly than the trees, shrubs, and grasses in nearby forests. The dry meadows and prairies can be burned cleanly and evenly, while snow may still be scattered throughout the forest understory and along the shaded edges of meadows. The likelihood of fire spreading into the denser vegetation is affected by such factors as wind, fuel types, the depth and density of cover, temperature, north-south exposure, and slope; but the most significant deterrent to the spread of fire is the greater moisture content of the fuel in the shaded, thick bush or forest. Directly linked to this are cooler temperatures and a higher above-surface relative humidity. Relative humidity is the easiest and most frequently measured variable for indicating differences in burning potential: in the grasslands it ranges from 25 to 35 percent, while under canopies of brush and trees it is from 45 to 55 percent.

Also important for spring burning is that soils are still damp or even frozen, with the result that surface fires do not injure the subterranean portions of dormant plants. Later on—at the peak of summer growth, for example—an intense grass fire will not only consume above-surface portions of plants but can also adversely affect tillering or damage root systems. Instead of stimulating seasonal growth, fires in late spring and throughout the summer will destroy existing growth and can significantly set back both grasslands and forests.

In northern Alberta, the potential for forest fires increases dramatically immediately following the safe-burning period. The driest months of the year are April, May, and much of June, and as forestry records show for recent years, the greatest number of forest fires—sometimes large ones—occur during the latter part of May through mid-June. Although these fires are caused predominantly by humans, they demonstrate the possibility of fire spreading from grasslands to bush after the early weeks of spring. The largest number of lightning-caused fires actually occur later, during the rainy season that extends from the latter part of June through July and August. With the greater heat of the midsummer months, these lightning fires are generally larger and more disruptive.

The act of firing itself—whether it involved a fire drill, flint and steel, or matches—was simple enough, but considerable knowledge was required to carry out controlled burning effectively and safely. Conditions differ from day to day, even hour to hour, and may vary within a single region.

All calculations included the particular time of day. At the onset of spring burning, fires might be set at midday to take advantage of higher tempera-

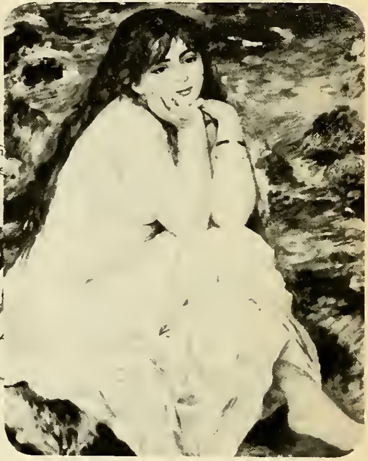
*Includes this Deluxe Album and 48-page Gallery Lecture Guide—at no extra cost*



GAZE in astonishment as Renoir's lovely "Seated Bather" (shown above) appears on your wall aglow with all the vibrant reds, blues and greens of the Impressionist palette. Or, thrill to Rembrandt's famed "Aristotle Contemplating the Bust of Homer"—one of the world's costliest works of art. Or, marvel as you view Titian's allegorical masterpiece "Sacred and Profane Love" just as it appears in Rome's Borghese Gallery.

Until today, unless you had the means to travel among the world's great museums and private collections, you simply could not know these paintings so *intimately*. Now, as a member of the *McGraw-Hill Color Slide Program of Art Enjoyment,* they are but a few of the magnificent art works you will enjoy and more richly understand as you view them in dramatic *full-size* and glowing *original colors!*

### Accept this $1 demonstration offer

If you mail the attached card, you will receive a unique Album containing 24 color slides of priceless works by Renoir, Monet, Degas and other important Impressionist painters. These exquisite slides are produced to exacting specifications in Florence on 35mm. Kodak film. They come in individual 2" x 2" mounts and can be used in any home slide projector. (If you do not own a projector, see special offer below.)

**The color slides, however, are only one part of this elaborate Album. Bound into the center is an illustrated 48-page book by Albert Chatelet, Director of France's renowned Lille Museum—with a guide to each of the slide pictures and the complete story of the Impressionist era.**

If this demonstration pleases you, you will be offered a new slide-and-commentary Album approximately every six weeks. Among the Albums in this series are *Italian Renaissance Painting*, the *Origins of Modern Art—Romanticism* and *Realism*—and other Albums covering every major art period.

### The cost is surprisingly low

The least you might expect to pay for 24 color slides of comparable quality—if the subjects were available from museums and private collections—is $18-$24. Yet, as a subscriber to this new Program, you pay only $12.95 for each complete Album—including slides and illustrated guide book. You may take as few or as many as you like, and may stop whenever you wish.

### Your Introductory Album only $1
### No obligation to continue

Send no money now. We will ship your introductory Color Slide Album of Impressionist Paintings and enroll you as a trial subscriber. If you are thrilled with the demonstration, send only $1, plus a few cents for tax and shipping. Thereafter, you will be offered a new Album approximately every six weeks at the subscribers' low price of only $12.95. If not delighted, however, you may return the Introductory Album within 15 days, and owe nothing. Mail the attached card today.

### *Here's what you get for only $1*

*Luncheon on the Grass*—Edouard Manet
*Women in the Garden*—Claude Monet
*The Green Parasol*—Berthe Morisot
*Nude in the Sun*—Auguste Renoir
*The Seated Bather*—Auguste Renoir
*The Pedicure*—Edgar Degas
*The Saint-Lazare Railroad Station*—Claude Monet

tures and reduced humidity. A week or two later in the season, fires would be set early in the morning or late in the evening to avoid drier conditions.

The year-to-year frequency with which grasslands were burned was important, since a meadow choked with several years' growth of weeds and brush presented greater problems than one regularly burned. Prairies and meadows with tall, verdant grasses were usually burned each year, whereas the sparser grasses found on sandy, poor soils were fired less frequently. The particular frequency of burning, like seasonality, is distinctively human and sets apart the Indian pattern of burning from the natural cycle of boreal forest fires.

Wind speed and direction were used to advantage, with a moderately strong wind favored for most burns. The overall size of an area was also taken into consideration. A small meadow or slough burned more quickly, reducing the risk that conditions would change before the burn could be completed. Normally, the large prairie-parklands were burned first, and these fires are described as sometimes having lasted several days.

Where the terrain sloped, more intense fires were achieved by burning uphill; less intense by burning down. A Cree-Métis explains:

> See, you start a fire at the top of a meadow in the afternoon, when you feel the wind change, the way the cool air does at that time. This way the fire burns toward the low part of the meadow where all the wet grasses are. And then it just goes out. It's safe. You have to know the wind. You have to know how to use it.

A combination of natural and manmade firebreaks was regularly employed. Streams, lakes, and bogs provided natural barriers, as did the higher humidity levels of brush and trees. Artificial firebreaks included adjacent burned areas, whose relatively drier fuels had been fired several days earlier. Also stands of brush and trees within a previously burned meadow could be intensively fired—sometimes weeks after the initial burn—with the aim of extending the area of grasslands or obtaining ready-dried firewood.

Because Indian campsites were established on the edges of grasslands, the fireproofing of campsites was an integral part of burning meadows and prairies in early spring. To protect the habitations, fires were set so as to first spot-burn within settlements and then burn outward, before running fires were set to clear the adjacent grasslands.

Finally, people could help control fires. Watersoaked spruce boughs were used by women and children to beat out flames at the edges of meadows and around settlements. Besides being relatively ineffective, however, this was considered unnecessary when control factors were understood and "things were done right." Similarly, the modern fire fighting equipment that is deployed at a controlled burn is there, not as part of the controls, but as a safeguard against an escaped, uncontrolled fire.

Although perhaps less than one percent of the total area burned each year, the largest number of fires involved grassy swales and sloughs. Such small fires, which could be carried out by one or two men, were set throughout the areas covered in the annual round of hunting and trapping. These grassy microhabitats within the boreal forest are important for predator and prey alike. A Slavey Indian discusses the concern for maintaining both grass and forested areas:

> Lots of animals that live in the forest come to the meadows and sloughs to hunt. Marten, like, they live in the woods but they hunt lots in the grassy places—specially for mice. So you don't want to burn the woods, just the sloughs and meadows.

The necessary foresight is evident in what another Slavey Indian has to say:

> Trappers burned when they were on their way home from spring hunting. At that time of year it was safe, and they burned because it made it better for them in the winter with more animals to hunt and trap for.

Not infrequently, the hunter-trapper passed through areas before they could be effectively burned, but this problem was partly offset by setting delayed fires. Campfires were left smoldering so that they would flame up when the grasses were sufficiently dry but the forest still wet. This is remembered by a Cree Indian:

> When we'd come off trapline, it might be too wet to burn the sloughs or creeks [creek beds]. So we'd just build a big campfire and leave it. Maybe couple of weeks later even, when the grass is really dry, the grasses would all get burned up, but the fire wouldn't go anywhere because it was still damp in the bush. We didn't worry about campfires in the springtime; but you had to be careful during the summer cause you could start a helluva big fire.

The ponds created by beavers and frequented by moose were of particular value to the Indians. Although some sloughs and streams were burned each year, beaver habitat was burned less frequently, as a Slavey Indian explains:

> It makes a lot of difference for the trapper if an area was once burned. It's easier to attract animals to these areas. As for the beaver, it takes a while before they move into an area that was burned; about four years after the burn. The reason it takes that long for the beaver to come to the burned places is that the aspen don't grow as fast as grass and some other plants that grow after a burn. It is good for the moose too.

Portions of northern Alberta are along the flyways of, and provide summer habitat for, enormous numbers of ducks and geese, and from May through September waterfowl were (and still are) a prime food source. The shorelines of ponds and lakes were fired so as to enhance them for the ducks and geese that fed there. A Slavey Indian describes the process:

> We always burned just before all of the snow melted, before the ducks had started to nest. But we didn't burn after the ducks had nested; we knew when to burn and when not to burn. The spring fires made things good for the ducks, and it was good for all kinds of other animals too.

Muskrat, important for their meat and fur, also depend upon shoreline habitats. "Muskrats like to eat the grass roots, like the reeds that grow round a lake or pond," says a Cree Métis. "When you burn them, the roots grow more and it makes it good for the muskrats." Because the reed and grass fringes of ponds and lakes contain more moisture than the open meadows, they were fired later in the spring burning period. In the absence of regular burning, marshy grasses become matted and die, part of the gradual process by which bodies of water are transformed into grasslands.

Like other forest types, the boreal forests contain deadfall areas where as a result of age, disease, and high winds, trees lie in tangled and nearly impenetrable jumbles. Such areas are all but devoid of game and are likely to ignite during summer lightning storms, threatening to involve the surrounding live forest in dangerous and destructive fires. A Cree Indian explains how, in the spring, the Indians fired such relatively dry deadfall areas:

> When you burn the deadfall places it burns for a long time, not like the meadows—they burn out fast. Because there's all those dead trees. Maybe the next year you come back, burn it some more, and then pretty soon it's all open and the moose really like those places.

As forests age, the intensity of fires increases substantially with the build-up of older trees, dead wood, and decaying plant material. In the normal course of events, older stands of trees and the accumulations of forest-floor litter are periodically removed and the forest thinned or regenerated as a result of lightning fires or, since the arrival of hunter-gatherers in the New World, man-made fires. Our historically recent attempts to eliminate all fires have resulted in greater and greater amounts of fuel and ever larger, more disruptive conflagrations. "This place used to be called First Prairie, and it was all open-like then. But now we got brush, trees, and you get a [summer] fire now and you got a helluva time," warns a Cree-Métis from Hay Lake. "Everything going to get burned up-like. When there were spring fires it wasn't so bad, even maybe you get a summer fire. But now. . . ."

The crown fires that annually destroy hundreds of thousands of acres of timber and brush—sometimes in fire storms with extreme temperatures of 570° to 750°F—were undoubtedly less common prior to 1900. This was because natural fires were unchecked, and because the Indians, through their practices of early spring or late fall burning, added to the diversity of plant communities. What ecologists have now clearly established is that mosaics of young-to-mature plant communities are better protected against the incursions of fire, disease, and bug infestation than are the more uniform, decadent stands of aging brush and trees.

The Indians' knowledge of the use and effects of burning was enriched by their religious and ethical beliefs, in a way perhaps similar to the conservation ethic valued by present-day naturalists. Despite differences in cultural emphases, Slavey, Beaver, Cree, and Chipewyan understood their forest habitats as complex, interrelated systems of causes and effects. They followed a practical, straightforward logic, and as with modern arguments in favor of the use of controlled burning, they recognized that selected and prescribed burning was not simply an imitation of the natural fire regime. "They must be very wise, eh? Those people? That time?" says one Beaver Indian woman. ☐

## Rentals

ADIRONDACK LODGES on Upper Saranac Lake. Available for two weeks or a month, July through September. Everything provided for comfortable living in the quiet woods. From $650 for two weeks. Please write Bartlett Carry Club, RFD 3, Tupper Lake, NY

FLORIDA LUXURY GULF CONDO. $325 per month, four month minimum, Oct-March, 2915 West 27th St Panama City, FL 32405

VIRGIN ISLANDS, Limestone Reef Terraces. Excellent view, service. Efficiencies $35, for 2. Island Vacations, RD 4, Princeton, NJ 08540. (201) 329-6309

## Resorts

FREE! Map/Birdlist—Chiricahua Mountains Area—plus illustrated brochure of our nature lovers' retreat—Cave Creek Ranch, Box F-1, Portal, AZ 85632

NEW MEXICO. Guided tours—wildflowers, birds, prehistoric dwellings. Bear Mountain Ranch, Silver City, NM 88061 (505) 538-2538

## Tours/Trips

ADIRONDACK WILDERNESS SKI TOURS—Enjoy the exhilaration and beauty of a northern winter in the company of expert naturalist guides. Each cross-country skiing vacation is five days. Limited to eight guests. Geared to beginners, intermediates and experts. Daily sojourns into the 18,000-acre St. Regis Wilderness Area and its "forever wild" lakes, ponds, forests and mountains. Excellent winter birding and chance to observe habitats of deer, beaver, bobcat, coyote, bear, fox, otter, pine marten, fisher, mink. Evenings spent in cozy backcountry lodge. Hearty homecooked meals. Fireside programs feature noted ecologists, historians, photographers, conservationists. Adirondack Ski Tours, McMaster Rd., Saranac Lake, NY 12983 (518) 891-1080

ADVENTURE—STUDY TOURS. England: Children's Literature; Nepal: Psychology and Meditation; India: Performing Arts; New Guinea: Arts Festival; Thailand, Burma, Sri Lanka and Nepal: Buddhism. Other unique study tours to Java and Bali; Spain and Israel; Eastern Europe and Russia; Africa; Mexico and Guatemala; Peru and Bolivia. Small Groups, expert leadership. College credit available. The Way of Travel, Inc. 507 Lincoln Street, Santa Cruz, CA 95060

ADVENTURES—OBSERVE WHALES during winter breeding, January through April, in Mexico's lagoons, Sea of Cortez, Maui Hawaii, and Hudson's Bay. Wildlife and natural history trip to Kenya, Zambia, Zaire, Rwanda, and Galapagos. Small groups conducted by expert leaders. Write for catalogue. Adventures International, 4421-N Albert, Oakland, CA 94619

BACKPACK THE SALMON RIVER WILDERNESS; the "River of No Return" wilderness of Idaho. Beautiful, rugged and wild. Trips for all abilities; running spring, summer and fall. College credit available. Small, personal groups. Write or phone: David Petersen, Wilderness Trails, P.O. Box 9252, Moscow, ID 83843 (208) 882-1955 or (208) 634-2794

CANOE ARCTIC. Fly-in canoe expeditions into the Heart of North America's last great wilderness—the tundra and taiga of Canada's Northwest Territories. Discover the warm dry summers, spectacular scenery, and unparalleled wildlife concentrations of a land untouched by man. Photograph caribou herds, white wolves, muskox, moose, grizzly, rich birdlife. Virgin fishing. Six person parties assembled and guided by Alex Hall, wildlife biologist and veteran arctic canoeist. All food and equipment provided. Previous canoeing experience an asset but not essential for all. Two-way radio. 12 days from $975; 18 days from $1275. For brochure write: Canoe Arctic Inc., 9 John Beck Cres. S., Brampton, Ontario, Canada L6W 2T2

CANOE TRIPS IN WILDERNESS NOVA SCOTIA, July-September. Small groups with licensed guides. Excellent food. Write: Granville Nickerson (N), RR4 Annapolis Royal, Nova Scotia BOS 1AO, Canada

DAYTRIPS IN EUROPE for do-it-yourself travelers! Let our unique publications guide you through unusually fascinating places. Ideal for railpass users. Free catalogue. Great Trips, Box 5199-N, New York, NY 10017

EVEREST AND SIKKIM 1980 nature treks with Bob and Linda Fleming, naturalists, authors ("Birds of Nepal; Kathmandu Valley"). Everest National Park. April-May (23 days). Sikkim (Kangchenjunga): Oct-Nov (25 days). Himalayan birds, mammals, plants, peaks, Sherpas. Nature Himalayas, 2726 Mockingbird, Kalamazoo, MI 49008

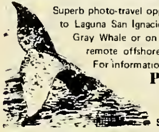
EXPEDITIONS are searching for team members. Register with ERI to make your experience available to expedition leaders. Archeology, Geology, Mountaineering, Oceanography, Ornithology, Paleontology, Sailing, Speleology, Zoology. Professors, institutions, expeditions, others use our research services for locating personnel and information on countries, permits, maps, equipment discounts, funding and more. Write: Expedition Research, Inc., Box 467N, Annapolis, MD 21404

EXPLORE GUATEMALA/PERU. Two-week hiking, canoeing and backpacking tours in Guatemala and Peru are designed to explore the natural wonders, archaeological treasures and diverse cultures of these extraordinary countries. Write: High Country Passage, Box 1100-NH, Hamilton, MT 59840

FASCINATING EGYPT/HOLY LAND/AFRICA: 10-day and longer trips, fully guided, for sophisticated travelers. Groups or Freelance. Forum Travel, 2437 Durant, Berkeley, CA 94704

HAWAII, NATURAL HISTORY TOUR Three islands. April 5-14, 1980. Golden Gate Audubon Society sponsored. Native birds, plants. Write: South American Wilderness Adventures, 1760-H Solano Avenue, Berkeley, CA 94707

**Wilderness Expeditions!**



Superb photo-travel opportunities on our 8 day voyages to Laguna San Ignacio, winter home of the California Gray Whale or on our 5 day expeditions to Baja's remote offshore islands. Group rates available. For information.

**Pacific Sea Fari Tours**

530 Broadway, Suite 1224 (N)
San Diego, CA 92101

## RATE AND STYLE INFORMATION

$1.75 per word; 16 word ($28) minimum. *Display classified* is $150 per inch. All advertisements must be prepaid. Rates are not structured for agency or frequency discounts. All advertisements are accepted at NATURAL HISTORY's discretion. Send check/money order payable to NATURAL HISTORY to: The Market, NATURAL HISTORY Magazine, Central Park West at 79th St., New York, NY 10024. Please include your personal address and telephone number, issue preferred, and suggested heading. Deadline—8th of month, two months prior to cover date (the January issue closes Nov. 8). Camera-ready art is required for display ads. A tearsheet or copy of the page with your ad will be sent upon publication.

Box numbers, telephone numbers, and hyphenated words count as two words; abbreviations and zip codes as one word each. All states are shown in two-letter code followed by zip, then telephone (with area code), if desired. Occasionally, slight editing is required for clarity. Thank you!

# A Star in Trouble

*Within our galaxy there is a star with unusual emissions that have puzzled astronomers around the world*

A star unlike any other previously known is under scrutiny by astronomers. Although still preliminary, the studies have inspired several imaginative theories and much commentary in the press. SS 433, as the star is known, has even been the subject of a monologue on the "Saturday Night Live" television program.

The most striking property of SS 433, and the one that has brought it such great notoriety, is the presence in the star's spectrum of pairs of emission lines, instead of single ones, with huge blue and red shifts. These pairs of lines are emitted by hot gas that is streaming away from the star in opposite directions at about one-fourth the speed of light. (The blue shift indicates matter approaching the earth; the red shift, matter receding from the earth. This phenomenon is known as the Doppler effect.) An emission line, a characteristic spectral signature of an element, appears as a bright, thin band in the spectrum—the array of colors, or wavelengths of radiant energy, that we see when white light passes through a prism. Large red shifts have been observed before, in distant galaxies and quasars, but this is the first known case of a large blue shift in any celestial spectrum, and the first case of a large red *or* blue shift in a star within our own Milky Way galaxy.

In the case of SS 433, the pairs of emission lines with red and blue shifts move constantly back and forth along the spectrum. The two lines of each pair always move in opposite directions. Thus the blue- and red-shifted lines of a pair sometimes actually cross each other, so that the hydrogen atoms, say, that were streaming toward the earth then stream in the opposite direction and vice versa.

The moving spectral lines of SS 433 were discovered by a team of California scientists led by Bruce Margon, an energetic young astronomer at the University of California at Los Angeles. After the initial observation was made on August 2, 1978, Margon persuaded colleagues from UCLA and from the Lick Observatory near San Jose, California, to record what he termed the "bizarre" spectrum at every opportunity. The team members ranged from a graduate student to a department chairman. With a battery of telescopes on Mount Hamilton, Mount Palomar, and Mount Wilson in California, and with another telescope on Kitt Peak in Arizona, they were able to observe SS 433 whenever circumstances permitted.

The spectrum of SS 433 is so unusual that at first Margon could not identify the atoms that emit three of the strongest spectral lines, although such identifications are usually duck soup for a professional astronomer. Even the physical process that shifted the lines was uncertain at that time. The California researchers considered the possibility that the familiar Doppler effect was at work; that is, that the line shifts were due to motions of the light-emitting matter. In the case of SS 433, however, the Doppler interpretation seemed unreasonable. The implied velocities of the light-emitting matter and, especially, the changes in velocity from week to week were considerably greater than those found before in any star.

Throughout the fall of 1978, the Californians monitored the curious spectrum of SS 433. Although the puzzling results had not yet been announced, I was given a preview on a late October visit to the control room of the four-meter telescope at Kitt Peak. There, Holland C. Ford, a UCLA astronomer noted for galaxy studies, punched some buttons and two spectra of the star appeared on a computer display screen. Ford had recorded them on two previous nights. Each had a different pattern from any spectrum I had seen before, and the differences between the two were pronounced.

By late fall the California team was examining the possibility that the star might possess an intense magnetic field, perhaps 100 million times stronger than the magnetic field of the earth. In so strong a field, spectral lines can split into pairs, each consisting of a blue-shifted and a red-shifted line. This process, called Zeeman splitting, is named for the Dutch physicist who discovered it when he placed a flame between the poles of a powerful electromagnet.

A second research team was already analyzing a critical test of the idea that Zeeman splitting produces the red and blue shifts in the spectrum of SS 433. According to known physical principles, if an intense magnetic field were present on SS 433, the emission lines would be circularly polarized. In circularly polarized light, the direction of vibration of the light waves rotates like the blade of an electric fan as the light wave travels through space. Led by James Liebert, an expert on polarized light astronomy at the University of Arizona, the second team had searched for circular polarization in the spectrum of SS 433. They found no measurable polarization and began to reexamine the idea that the huge line shifts are produced by the Doppler effect.

In particular, the Arizona group (which also included astronomers from the Universities of Michigan and Toronto) reasoned that if the line shifts were due to the Doppler effect, all the lines should be affected in a similar manner. In other words, if one line were red shifted by 10 percent in wavelength, then every other red-shifted line should be shifted by a like percent. The early Arizona data on SS 433 seemed roughly consistent with this Doppler interpretation, although there were uncertainties. The astronomers felt that they needed further spectra in

**by Stephen P. Maran**

order to tell whether, when the lines moved along the spectrum, their new red shifts would again correspond to equal percentages of their wavelengths. Unfortunately, as the earth revolved around the sun, SS 433 soon became unobservable. In California and Arizona, the two groups impatiently awaited the late winter when, due to the earth's motion, SS 433 would again be in view.

The Arizona team was able to reobserve SS 433 in late February 1979, while the California astronomers did not get a crack at it until mid-March. As Margon later described it to me, the mid-March spectra, obtained at Lick Observatory, had caught SS 433 in a phase when the red and blue shifts were relatively small. Each emission line pair was then closely spaced and there could be no doubt of the true, unshifted wavelengths. This made the identification of the emitting atoms certain. Additionally, it was now obvious that the lines were not simply pairs. They were triplets, each consisting of a central, so-called stationary line, and the noticeably changing red- and blue-shifted members. The pattern was in complete agreement with the expectations of Doppler theory, as was already recognized by the Arizonans, but there was no explanation for the very rapid velocity of the matter that produces the shifting lines or for the changes in the line shifts.

If the Arizonans reached their conclusion first, the Californians had an equally interesting finding. Plotting a graph of the velocities corresponding to all the line shifts on all the dates of observation, they found that the lines were shifting back and forth in a repetitive manner, with a period of about 160 days.

Theoretical astrophysicists struggled to explain what kind of moving, luminous matter might be connected with SS 433 and produce the large and

periodically changing Doppler shifts. One class of theories ascribed the spectral lines and their peregrinations to a thin ring of luminous gas, wobbling in space like the rim of a spinning, leaning top, each wobble lasting 160 days. Matter circulating around the postulated ring at high speed would move toward the observer along half the circuit, producing blue-shifted lines, and then recede around the other half ring, generating red-shifted emissions.

According to the ring theories, as proposed in various forms by theorists in England, Israel, and the United States, SS 433 is a giant black hole, with a mass of 100,000 to a million times that of our sun. Surrounding the hole, it is supposed, is the ring that (depending on which learned speculator one consults) consists either of matter sucked up from the thin gas of interstellar space by the powerful gravity of the black hole or of material drawn out from an unfortunate companion star or planet, doomed to circle the hole as its guts are inexorably extracted by the same immense force.

The menace of a giant black hole can be disregarded, I'm relieved to say, thanks to recent findings by three expert observational astronomers in British Columbia. Led by David Crampton of the Dominion Astrophysical Observatory in Victoria, the three made a detailed study of the "stationary" lines of SS 433. Last August they reported that even these lines shift back and forth in the spectrum, although by rather small amounts. This shifting has a period of thirteen days and almost surely represents the orbital motion of a binary star. Analysis of the orbital motion shows that the two stars in the binary are each no more than about twice as massive as our sun. Thus, the posited enormously massive black hole can be ruled out. Within a week of the Canadian report, the thirteen-day periodicity was confirmed by two physicists from the University of Oregon, who found a variation of similar period in the brightness of SS 433.

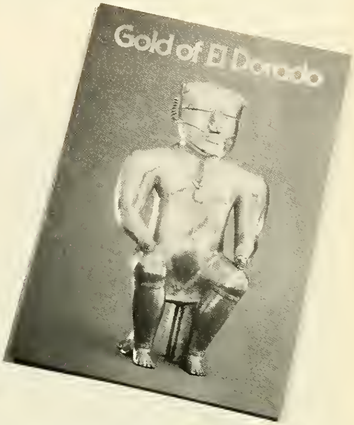
In line with current thinking, one member of the SS 433 binary system is a relatively normal star, while the other is a highly condensed object, probably a neutron star or white dwarf. According to this theory (of which there are several variations), the normal star is losing matter to its condensed companion. As the transferred mass spirals inward to the smaller star, it forms a hot, flat gaseous structure, called an accretion disk. Near the hub of the disk, or perhaps even at the central position of the condensed star, a fraction of the accreting gas is expelled at right angles, above and below the disk, possibly by pressure from gas or radiation or by magnetic forces. At any given time, one jet of gas produces light with blue-shifted spectral lines, as seen from the earth, while the oppositely directed jet emits the red-shifted lines. The accretion disk wobbles, causing the two jets to trace out cones in the sky once every 160 days. Thus, the highly shifted and noticeably changing spectral lines studied by the California and Arizona groups come from the jets of matter. The stationary lines are emitted elsewhere, perhaps from gas streaming between the two stars of the binary system. Such a gas stream would revolve with respect to our line of sight once every thirteen days, as the two stars go around their orbits.

The foregoing is a necessarily condensed account of the findings about SS 433, which is also a source of radio, infrared, and X-ray radiation. The star is under study with a wide variety of telescopes on the earth and in space satellites. From the visible-light studies that I have described, we now know that it is a sort of giant lawn sprinkler in the sky, spraying hot gas out in two revolving streams. The next question is, Where did it come from?

Maps of the surrounding area made with radio telescopes show that SS 433 is in the direction of the central region of a supernova remnant called W50. The latter is the expanding cloud of gas ejected in the explosion of a massive star perhaps 20,000 to 30,000 years ago. It seems likely that the condensed object of the SS 433 binary system is the remaining core of this exploded star. Although a mere cinder of its former self, the core is feeding on the substance of its companion star. This process is inherently unstable and cannot go on forever. By an as yet uncertain means, the core is also converting some of this feedstock into the high-speed jets that wobble slowly as they shoot out into space, signaling across the galaxy that out there, there exists what UCLA's Margon once termed a "star in some terribly weird kind of trouble."

*Stephen P. Maran is senior staff scientist in the Laboratory for Astronomy and Solar Physics at NASA's Goddard Space Flight Center in Greenbelt, Maryland.*

# An Art Book That Took Centuries To Create



It took the American Museum of Natural History four years to arrange its exceptional exhibition of more than 500 pieces of ancient gold from Colombia. But those few years are a brief time when compared with the decades archeologists have spent digging (literally!) and studying the gold artifacts from tombs, caves, and buried sites. And all that time is short when compared with the many centuries prehistoric Indians practiced their craftsmanship and artistry to create these treasures.

So when it became the United States sponsor for this outstanding collection, the American Museum faced a dilemma. Could we do justice to all this effort and scholarship and beauty? We think we have. First, by dramatically displaying *Gold of El Dorado: The Heritage of Colombia* in one of our largest halls. The glowing reports from visitors tell us our efforts have been worthwhile. If you don't have a chance to see the show for yourself in New York, we hope you will see it in Chicago, San Francisco, or New Orleans on its year and a half tour.

The second challenge for the American Museum was the creation of an appropriate book to accompany the exhibition. We decided against a traditional catalog; against a small, boring volume with tiny black-and-white pictures that could never do justice to these fine objects. Instead, we decided to present a select number of the finest pieces of pre-Columbian gold in a large, stunning format. And to represent the three important elements that make a great art book we chose outstanding professionals.

First, photographer Lee Boltin. One of the greatest photographers of art objects, he also took the famous pictures of the Tutankhamun show. We sent him abroad to find and record great pieces of pre-Columbian art.

Second, archeologist Warwick Bray, from the University of London. One of the world's foremost authorities on pre-Columbian art, Bray is also a skilled writer, able to present fascinating background in a succinct, readable essay in the book. Dr. Bray organized the Colombian gold exhibition in London.

Third, Harry N. Abrams, Inc., America's leading publisher of fine art books. In a co-publishing venture with the American Museum, Abrams designed the book, supervised the preparation of 30 large color plates, and monitored the fine-quality printing.

The result is an unprecedented exhibition book. It is bold and big—each plate is 16 by 11½ inches—bigger than this magazine *opened up*. The paper is heavier than most posters. In fact, many persons have purchased two copies of the book in order to have one set of these fine art prints for framing.

And now for the happy ending. Because the Museum is a co-publisher, we are able to offer this soft-bound art book at a major savings from its normal retail price of $12.50. We are pleased to offer *Gold of El Dorado* to subscribers for only $8.95—a 28% savings off its regular price. This special offer is valid only during the exhibition and only while our limited supply lasts. We suggest that you order one or more copies immediately. Of course, if you are not satisfied after you have had an opportunity to examine it in your home, simply return the book and the Museum will refund the purchase price.

# Celestial Events

### by Thomas D. Nicholson

**Sun and Moon** The sun is in the constellation Sagittarius in early January, moves into Capricornus on about the 19th, and into Aquarius by mid-February. Although the sun passed the winter solstice on December 22 (the "shortest" day of the year), the latest sunrise doesn't occur until January 4. While the time of sunrise changes little in January, sunset will come noticeably later, causing daylight to lengthen rapidly in the evening.

The moon is nearly full at the beginning of the month and quickly moves into the morning sky. It will present an exceptional view as it moves past Regulus, Mars, Jupiter, and Saturn from January 5 to 9 and again from February 1 to 4. January phases are: full on the 2nd, last-quarter on the 10th, new on the 17th, first-quarter on the 24th, full again on the 31st. In February, last-quarter is on the 9th, new moon on the 16th. Apogee (when the moon is farthest from the earth) is on the 8th in January, 4th in February. Perigee (nearest the earth) is on January 19 and February 17.

**Stars and Planets** Venus is brightening and moving into the part of the ecliptic that keeps it high above the horizon after sundown. It becomes very prominent in January, appearing higher and remaining later each night. Look in the west soon after sunset. After Venus sets, look for Mars, Jupiter, and Saturn to rise in the east, beginning about 9:00 P.M. Those three objects, together with the star Regulus to their right, make an exceptional sight from about 10:00 P.M., when they are well up in the southeast, until dawn. Jupiter is the brightest among them, Mars is next and brightening rapidly; Regulus to their right and Saturn to their left are about equally bright.

January 3: The earth is at perihelion, nearest the sun.

January 5–9: The waning moon is nearest Regulus on the night of the 5th, Mars and Jupiter on the 6th, and Saturn on the 7th and 8th.

January 7: Saturn begins its retrograde (westerly) motion.

January 17: Mars begins its retrograde motion. All three planets in the late night sky, Mars, Jupiter, and Saturn, are now moving westerly (retrograde). This will take all of them slowly closer to the star Regulus, while Mars moves closer to Jupiter, and both Mars and Jupiter move slowly away from Saturn. You can readily see these changes taking place if you watch them during the weeks ahead.

January 19–20: The crescent moon and Venus will present an interesting view in the early evening sky.

January 21: Mercury is at superior conjunction, in line with but beyond the sun, and it now enters the evening sky.

January 26: The bright star near the moon is Aldebaran in Taurus. About midnight, the moon covers Aldebaran, an occultation visible to observers in the southern United States.

February 1–4: The moon again moves past Regulus, Jupiter, Mars, and Saturn, presenting a dramatic view each successive night from about 9:00 P.M. until dawn. The three planets and Regulus are even closer to one another than in January, and Jupiter and Mars are exceptionally bright.

February 16: A total solar eclipse occurs today in Central Africa. It will be partial over large areas of Europe, Africa, and Asia.

February 17: Perigee moon occurs 24 hours after new moon, enhancing the normally stronger spring tides today.

★ Hold the Star Map so the compass direction you face is at the bottom; then match the stars in the lower half of the map with those in the sky near the horizon. The map is for 11:15 P.M. on January 1; 10:20 P.M. on January 15; 9:15 P.M. on January 31; and 8:15 P.M. on February 15; but it can also be used for an hour before and after those times.

# At the Museum

## *Gift of Akeley memorabilia includes unpublished Congo journals*

On the last page of the 1977–78 Annual Report of the American Museum of Natural History is a short list of "Gifts-in-Kind, Over $1,000" that includes, among other things, "one carved skull rack from the Papuan Gulf," "six jeremejevites," "92 snuff bottles," and "notebooks, pictures, and other memorabilia of the late Carl Akeley."

Carl Akeley, as many Museum visitors know, designed and collected for the Akeley Hall of African Mammals. In the early 1920s he revolutionized the art of taxidermy by replacing the traditional stuffing—which became lumpy and insect infested over time—with a sculptured model of the animal's body over which the skin was stretched. To mount the Museum's African elephants, Akeley invented a mechanism that combined cement with air and sprayed the foamlike mixture on a supportive frame. Dissatisfied with the movie cameras he used on his first African expedition, he designed and built one more to his taste; with it he took the first motion pictures ever made of gorillas. Akeley died in 1926 while on a collecting expedition in Africa.

The Akeley memorabilia, a gift from the estate of Akeley's second wife, Mary L. Jobe Akeley, arrived late in 1977 in two cardboard boxes, which were stored in a dark corner of the Rare Book Room. The boxes were opened, but nothing was removed or cataloged until last fall, when Nina Root, the chief librarian, decided to examine their contents.

The boxes were filled with yellowing folders stuffed with letters and notes, crumbling journals and notebooks held together with silk ribbons, hand-tinted glass lantern slides, photographs, newspaper clippings, and autographed books.

Most of the material, it turned out, did not concern Carl Akeley at all, but Mary L. Jobe Akeley—a well-known explorer, mountaineer, and educator, who had already led six expeditions to the Canadian Northwest before she married Akeley in 1924. Mary L. Jobe was the first person to map the headwaters of the Fraser River and the glaciers of Mount Sir Alexander. She had made several first ascents, and the Canadian government christened a peak in the Rockies "Mount Jobe" in her honor. Like most explorers, she kept notebooks while in the field. In one small notebook, marked *1917–18 Trail Notes Enroute. Wapiti*, she had recorded the progress of an early expedition to Alberta. Every square millimeter of the notebook was filled with a dense, almost illegible hand.

> Oct. 15. Rode up to timberline at snow line—It began to snow—[illegible] Blue horse played out—Steep going—Drifts waist deep—fell every 10th step—C. hardly make Blue go—Finally made summit—Heavy snow. . . . Steep coming down—Fell over rock head down—6 ft—Black & blue—Jack falling constantly—Horses overtired. . . .
>
> Oct. 17. Awake at 6—Not a great deal of sleeping—Much groaning—Very snowy but clear—Temperature 16° above zero—Breakfast of bacon, peas, green [illegible] flap jacks. . . .
>
> Oct. 18. C. up at 5:30—I lay until 6:15—H.G. terribly cold all night—slept little—Jack awake and groaning most of night—Dreamed of eating chicken at the Mitchell's. . . .

Six years and several expeditions later, Mary L. Jobe married Carl Akeley, and some of her notebooks did concern him. In 1926 she accompanied him on the Akeley-Eastman-Pomeroy Expedition to West Africa to collect and photograph for the proposed African mammal hall at the Museum. A bundle of journals, tied with a red silk ribbon, covered this expedition. Inside the front cover of the last journal was scribbled, "Kivu—High Camp on Slopes of Mt. Mikeno. Nov. 14 et Seq."

> [Nov. 14, 1926] It was cold & it poured rain. With the exception of a few moments of sunshine each day, where for a brief period the clouds lifted so that we could see Lake Kivu and also the two volcanoes Nyamlagira and Nyiragongo. The craters we could see plainly almost every night as its fiery furnace of boiling lava illuminated the clouds & sky or as flames shot into the heavens. . . .
>
> Looking out of my tent it occasionally seemed as if I were standing on the brink of a gulf. The clouds were so dense & as if the whole world were falling away from me—at such times I could hear the song of the thrush. . . .

The expedition stayed for several days at a camp on the saddle between Mount Mikeno and the volcano Karisimbi. Akeley was nauseated but insisted on moving to their next camp.

> When about ¼ mi. away from the saddle camp he [Akelely] stopped the boys & said he was cold & would wait. It was dismal, wet and dark just there so he walked back to camp & sat down under the fly of the work tent. . . . He talked energetically about the gorillas there. . . . Soon he began to shake with a chill. In about half an hour he began to get worse—then [illegible] fever came & he ran a temperature of 103. This I controlled & in about three hours, a little after dark, he was normal. . . . The next morning [Nov. 16] he said he had not slept at all & was again nauseated & could take no nourishment. . . . There was a

**Evening Lecture Series**

Africa has long served as a vast, outdoor laboratory for the study of animal behavior. Richard Van Gelder will lead off the "Winter 1980 Adult Evening Lecture Series" with *The Greatest Show on Earth*. In eight slide-illustrated lectures, Van Gelder will expose the private lives and loves of a wide variety of African mammals, from the matriarchies of elephants and the harems of baboons to the solitary habits of leopards and the hunting-pack strategies of wild dogs. Van Gelder travels frequently to Africa, both for the Museum's Discovery Tour program and as a research scientist and curator in the Department of Mammalogy.

In a second series, Malcolm Arth, anthropologist and curator in the Department of Education, will explore a wide range of human behavior in the 1980 "Anthropology Through Films" program. The featured guests will be filmmaker-anthropologists who will discuss their work and answer questions from the audience. In one program, Robert Gardner will show *Deep Hearts*, his new film about a ceremony among the Bororo people of Niger in which men compete to be selected as the most nearly perfect. On another evening, guests David and Judith MacDougall will screen and discuss their 1976 film, *The Wedding Camels*, which reveals the complex progress of a marriage in the making among the Turkana people of East Africa.

These are just two of the many

heavy hailstorm. I kept Carl warm and gave him hot water which was all he could take. I said to him in the A.M., "Well, I have got them all hard at work, if that is any consolation." He said, "It doesn't seem to matter now. But out it will in the long run. I know." I asked him, when [illegible] if he wanted me to stay with him—if "he were afraid." He laughed a little laugh and said, "No honey, I am not afraid."

[Nov. 17] From 9 to 11:30 he seemed quite comfortable but very weak. . . . I propped him up on extra pillows & put pillows under each arm. His eyes seemed looking far up Karisimbi. . . . I could still feel his pulse faintly in his wrist but more pronounced in his neck. Derscheid [a Belgian zoologist and doctor who accompanied the expedition] gave him more caffeine, believing he was in a stupor. But as he never reacted to it, his soul must have passed. . . . It was not, however, until 2:30 that we could believe he was gone. . . . For four days our boys worked excavating a tomb for him out of the lava rock on a high point above our tents. . . .

After Carl Akeley died, Mary Akeley took charge of the expedition; for five more weeks she continued to collect and photograph despite torrential rains and the desertions of workers. When she returned from Africa, King Albert of Belgium called her to Brussels and bestowed upon her the Cross of the Knight of the Order of Belgium in recognition of her achievements.

Mary Akeley explored, collected, and mapped in the Congo, Zululand, the Transvaal, East Africa, and Canada until age forced her to limit her activities. She was 80 years old when she died in Mystic, Connecticut, in 1966.

If you visit the Museum you can glimpse the two volcanoes Mary Akeley describes in her journal. In the Akeley Hall of African Mammals, behind the magnificent gorillas collected and mounted by Carl Akeley, there is a panoramic view of Nyamlagira and Nyiragongo. The painting is based on a photograph Akeley took near the spot where he was later buried. Once while passing this break in the trees, which he thought was the most beautiful spot in all of Africa, Akeley turned to his wife and said, "Do you see now where the fairies dance?"

*Douglas J. Preston*

lecture series and field trips offered by the Department of Education this winter and spring. To obtain a brochure and registration form for the lecture series and field trips, write to the Department of Education at the Museum or call (212) 873-7507.

**Discovery Tours**

Participants on the Museum's 1980 *Voyage to Classical Lands* depart February 20 aboard the m.t.s. *Orion* to visit Egypt and Israel. Accompanied by Museum scientists and lecturers, tour members will learn about the history, archeology, and geology of the area as they cruise through the Suez Canal and into the Gulf of Aqaba. Prices, which include air fare, range from $2,700 to $3,300 per person, double occupancy.

The *Orion* is one of many ships the Museum has engaged for its 1980 Discovery Tour program. Travelers on the *Nile Cruises* (several are offered) will board flat-bottomed boats and sail up the Nile River, visiting Thebes, Karnak, the Valley of the Kings, and other historical sites. In September, ornithologist Mary LeCroy will lead tour members on a houseboat trip down New Guinea's Sepik River as part of the *Anthropology and Ornithology Tour of New Guinea and Australia*. Participants on the *Mongolia and Central Asia* tour in June will take to the water to explore the natural history of Lake Baikal in Irkutsk, Siberia.

For more information about tours and itineraries, write to Discovery Tours at the Museum.

**Music of the Andes**

*Tahuantinsuyo*, a group of traditional musicians from South America, will offer an evening of music from the Andes on Wednesday, January 9, at 7:30 P.M. in the Auditorium. The program will be accompanied by dances from the highlands of Colombia and slides of the life and scenery of the Andes. Tickets for *Tahuantinsuyo* are $7.00. For information on ticket availability call (212) 873-7507.

**Guided Tours**

The Museum offers free tours, led by Museum volunteers, to give visitors an inside glimpse of the history of the Museum and to provide an introduction to the Museum's vast collections. Visitors may join the *Highlights and History Tours* at the second floor Information Desk in late morning or early afternoon. Inquire at the desk for specific times on the day of your visit.

**Worlds in Balance**

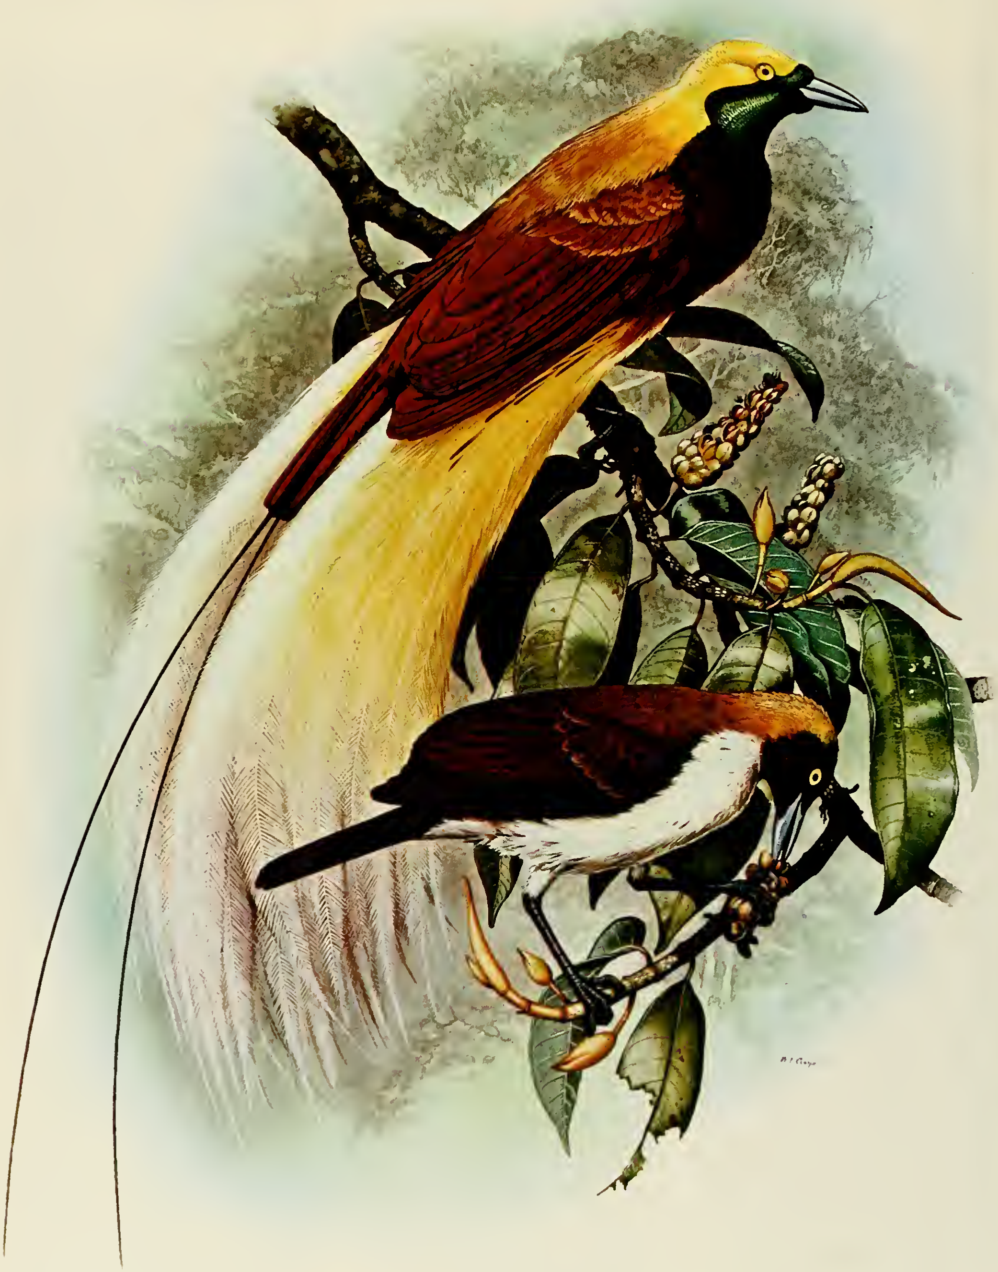
For the January Members' Program, George Schaller, author of *Mountain Monarchs* and other books on endangered habitats, will compare two widely different ecological systems and the challenges they offer to scientists, governments, and conservationists. The swamps of the Mato Grosso south of the Amazon and the fragile environment of the high Himalayas will be the subjects of his slide-illustrated talk, for which he will draw on his own scientific work and conservation efforts in both areas. *The Himalayas and the Amazon: Endangered Habitats at Two Extremes* will be presented on Wednesday, January 16, at 7:30 P.M. in the Auditorium. Members are admitted free; nonmembers may purchase tickets for $3.00 at the door.

**Puppet Show**

Puppeteer Eric Bass will present *The World of Little Kasper* on Sunday, January 20, at 2:00 P.M. in the Auditorium. The show, for children over six and adults, is a series of tragicomic vignettes featuring Little Kasper, a three-foot puppet character based on a German folk hero. Little Kasper sings, dances, plays the xylophone, and experiences the vicissitudes of life. Phyllis A. Ehrlich in the *New York Times* calls *The World of Little Kasper* "sophisticated and humorous." Members are admitted free; nonmembers may purchase tickets for $2.50 at the door. For more information, call (212) 873-1327.

**The Big Step**

*Colony in Space* will return to the Hayden Planetarium after *Star of Wonder* closes January 8. *Colony in Space*, which premiered at the Planetarium last September, explores how human beings may first colonize outer space in the early twenty-first century.



*Lesser Bird of Paradise*

by Mary LeCroy

# New Guinea Jewels

The Birds of Paradise and Bower Birds, by William T. Cooper and Joseph M. Forshaw, *David R. Godine, Publisher, $150.00; 304 pp., illus.*

An exquisite folio volume, *The Birds of Paradise and Bower Birds* is now available in the United States for the first time, although it was originally published in Australia in 1977. David Godine is well known in this country for publishing fine books, and the present volume is no exception. It immediately invites comparison with nineteenth-century volumes featuring hand-colored lithographs. More specifically, from 1891 to 1898 Bowdler Sharpe published a monograph on birds of paradise and bower birds using plates prepared by the then recently deceased John Gould and adding plates by other artists. This treatise was very expensive even then and a limited number of copies were produced. The few complete sets that remain are for the most part difficult of access. Since then no volume has accurately portrayed the birds of paradise and bower birds in color.

William Cooper's paintings are in many ways reminiscent of Gould's—a distant, pastel forest shrouded in mist forms a backdrop for the brilliant, jewellike colors of the birds themselves. The earlier artists had meager knowledge of the birds in life and had to rely on museum skins and snatches of field notes, but Cooper has made a number of trips to Papua New Guinea to study the birds in their natural habitats. His plates reflect this firsthand knowledge not only in the birds themselves but also in the vegetation, the candid pencil sketches, and the many field notes quoted in the text. Having seen the original paintings for this volume, I can appreciate that some of the subtleties of color, iridescence, and

ATTACK CAT

WALL HANGING IN FINEST GENUINE COWHIDE

**magnificently silk-screened by hand**

There he is 'meditating' among the flowers. Is he ready to purr—OR TO POUNCE?? You never know with a cat, so it's best to warn everybody that his eyes are upon them. Beautifully detailed, thick genuine cowhide wall hanging captures all the mystery and grace of the world's most wonderfully wiley animal. Superbly hand silk-screened with rich, earthy colors. Casts a magical, feline spell in living room, bedroom, entry hall or den. 12"x15" with real leather thong.

**Only $7.50 Gift Special! 2 for $14.00**

*A must for every home that's guarded—and governed—by a cat!*

Inside Mongolia & Central Asia

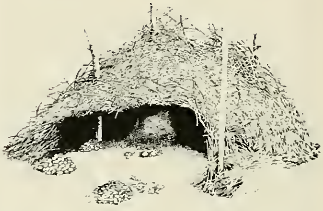
May 31 to June 21, 1980

American Museum of Natural History
**Discovery Tours**

Discover the Gobi, Central Asia & Siberia with the American Museum of Natural History. An outstanding experience with colorful costumes and bazaars, impressive monuments and architecture. Visit yurt camps and dinosaur bone sites, and the deepest fresh water lake in the world. The itinerary includes Moscow, Samarkand, Bukhara, Tashkent, Irkutsk, the Gobi and Karakorum. Tour price: $3041 per person. For further information write to Discovery Tours, American Museum of Natural History, Central Park West at 79 St., New York, NY 10024 or call (212) 873-1440.

deep, velvety black are lost in the printing process. But I doubt that any greater fidelity to the original is possible, short of the hand-colored plates of the last century. The present plates are very beautiful indeed, and the edition is a collector's item.

Joseph Forshaw states in the introduction that this volume is designed to supplement and illustrate in color the standard work on these two families, *Birds of Paradise and Bower Birds*, by E.T. Gilliard (Natural History Press, 1969), which is still available. Therefore, much of the material covered in the Gilliard volume and most of the theoretical considerations are omitted from the present work. An introductory chapter orients the reader, and write-ups of individual species give a good general account of subspecies, distribution, general life history, and reproduction. Included in these species accounts is much recent (post-1969) information, some presented here for the first time. Of particular importance are Cooper's recent field observations of display and mating sequences of several species.



This, then, is not just a picture book. Although the text is in one sense a vehicle for the plates, the plates and text together make it possible, for the first time in two generations, for the public to glimpse the almost unbelievable beauty, diversity of form, and unique behavioral patterns of these two fascinating families. Unfortunately, the cost will put this volume out of the reach of many, but we may hope that a smaller, less expensive edition will be forthcoming, as was the case with Forshaw and Cooper's *Parrots of the World*. The new information in the text deserves a wider audience.

*Mary LeCroy, a member of the scientific staff of the Department of Ornithology at the American Museum of Natural History, is the author or coauthor of fourteen articles on New Guinea birds.*

# EVENING LECTURE SERIES FOR ADULTS STARTING FEBRUARY, 1980

American
Museum of
Natural
History

**THE GREATEST SHOW ON EARTH**—8 Tuesdays starting February 19, 7:30-9:00 p.m. Fee: $40. Main Auditorium.

"The Greatest Show on Earth" exists in Africa, where some of the world's greatest populations of spectacular wildlife may still be seen. Africa has long served as a vast, outdoor laboratory for studying the behavior of wild animals. In this slide-illustrated series, study the fascinating private lives of mammals, from the matriarchies of elephants to the monogamies of dik-diks; from the harems of baboons and zebras to the female-lib. society of hyenas; from the solitary lives of leopards and rhinos to the aggressive aggregations of hyraxes and the peaceful assemblies of nyalas. Dr. Richard Van Gelder, Curator of Mammals has studied the behavior of African mammals since 1968 and leads the Museum's Discovery Tours to Africa.

**ANTHROPOLOGY THROUGH FILMS**—6 Thursdays starting February 14, 7:00-9:00 p.m. Fee: $35. Main Auditorium.

Six evenings of extraordinary films selected and discussed by Dr. Malcolm Arth, anthropologist and curator, which provide insight into culture and human behavior. Filmmakers John Cohen, Robert Gardner, David and Judith MacDougall; and anthropologist Rhoda Metraux will be special guests during the series which includes the films: Qeros: The Shape of Survival; Eduardo The Healer; Italian-American; Cotton Candy and Elephant Stuff; Deep Hearts; Reflections: Margaret Mead; and The Wedding Camels.

**FORAGING FOR DINNER: IDENTIFYING COLLECTING AND PREPARING WILD FOODS**—8 Mondays starting February 25, 7:00-8:30 p.m. Fee: $40.

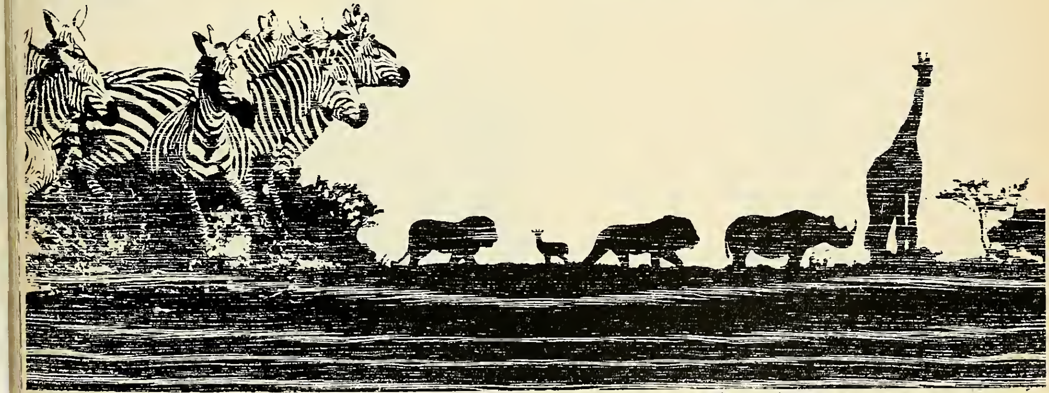
Get to know your wild plants that have been used for food by various peoples throughout the ages. In this series of lectures, supplemented with slides and demonstrations, Dr. Helen Ross Russell, author of the book *Foraging For Dinner*, examines these wild plants, their cultural history and methods of preparing the more common ones.

**MUSHROOMS, MOSSES, FERNS, AND OTHER NON-FLOWERING PLANTS**—5 Mondays starting February 25, 7:00-8:30 p.m. Fee: $20.

The non-flowering plants range from microscopic bacteria to gigantic kelps and conifers. In this slide-illustrated series, Helmut Schiller, Lecturer in Botany at the Museum, introduces diverse plants: mushrooms, mosses and ferns of forest floors and meadows; lichens of rocky and sandy places; algae at the edge of the sea; and conifers.

**ANIMAL LIFE IN NORTHEASTERN UNITED STATES**—8 Thursdays starting February 14, 7:00-8:30 p.m. Fee: $40.

Using color slides and recordings, Kenneth A. Chambers, Lecturer in Zoology at the Museum and author of *A Country Lover's Guide to Wildlife*, introduces the exciting variety of amphibians, reptiles, birds and mammals to be found in the New Jersey Pine Barrens, the Adirondacks of New York, and other remote areas in New England.



please print

**Advance Registration** is requested but registration will be accepted on the opening night if the course is not filled. **No single admission tickets will be sold.**

NOTE: Participating and Donor members may take a 10% discount on open enrollment courses. *Associate Members are not eligible for the discount.* For further membership information, contact the Membership Secretary, 873-1327.

# Additional Reading

**Desert Shrew** (p. 46)

A summary of scientific data and references on the desert shrew can be found in "*Notiosorex crawfordi*," by David M. Armstrong and J. Knox Jones, Jr. (*Mammalian Species*, November 29, 1972, pp. 1–5, published by the American Society of Mammals). *Sierra Nevada*, a natural history of the desert by Verna R. Johnston. (Boston: Houghton Mifflin Co., 1970), has a small section on shrews. The biological rhythms of dusky shrews are discussed on page 96 of *Mammals of the Pacific States*, by Lloyd Ingles (Stanford: Stanford University Press, 1965). Illustrated by the author, Konrad Z. Lorenz, *King Solomon's Ring* (New York: Apollo Editions, 1961) is an anecdotal natural history of a variety of animals, including shrews. *Desert Animals: Physiological Problems of Heat and Water*, by Knut Schmidt-Nielsen (Oxford: Clarendon Press, 1964), explains how animals survive in the desert. "Of Libyan Jirds and Fat Sand Rats," by Martin Daly (*Natural History*, February 1979), is about another small desert animal.

**Spiders** (p. 56)

A classic natural history of spiders by the great nineteenth-century naturalist J. Henri Fabre, *The Life of the Spider* (New York: Horizon Press, 1971) gives detailed descriptions of the curiosities of spider behavior. *The Common Spiders of the United States*, by James H. Emerton (New York: Dover Publications, 1961), is an introduction to American spiders (first published in 1902 by Ginn and Company). Spiders' habits, life histories, morphologies, numbers, and kinds are discussed in *American Spiders*, by Willis J. Gertsch (Princeton: D. Van Nostrand Co., 1949). *The Spider Book*, by John Henry Comstock, revised and edited by W. J. Gertsch (Ithaca: Cornell University Press, 1975), is a guide for amateurs and beginning students to the structure, habits, and classification of American arachnids (first published in 1912). An inexpensive guide is *How to Know the Spiders*, by B. J. Kaston (Dubuque: William C. Brown Co., 1978). For scientific articles see the *Journal of Arachnology*, published three times a year by the American Arachnological Society in cooperation with the Graduate School, Texas Technological University.

**Galápagos Fish** (p. 62)

"The Eye Structure of the Four-eyed Blenny, *Dialommus fuscus* Gilbert," by C. M. Breder, Jr., and E. B. Gresser (*Zoologica*, vol. 24, 1939, pp. 239–44), was the first published anatomical description of the species, based on a preserved specimen. J. B. Graham's "Aerial Vision in Amphibious Fishes," (*Fauna*, vol. 3, no. 1, 1971, pp. 14–23), is a colorfully illustrated review of amphibious and aerial vision. Other marine creatures of the Galápagos Islands are featured in "Undersea Wonders of the Galápagos," by Gerard Wellington, with photographs by David Doubilet (*National Geographic*, September 1978, pp. 363–81). See also "The Four-Eyed Fish Sees All," by Thomas O'Neill, with photos by Paul A. Zahl (*National Geographic*, March 1978, pp. 390–95). *Galápagos World's End*, by William Beebe (New York: G. P. Putnam's Sons, 1924), is a readable natural history with some discussion of marine life. More scientific, *The Galápagos: Proceedings of the Symposia of the Galápagos International Scientific Project*, edited by Robert I. Bowman (Berkeley: University of California Press, 1966), includes papers on Galápagos sea life.

*Boeotian female clay figure, seventh century* B.C.

M. Chuzeville, Musée du Louvre

**Swastika** (p. 68)

Most available books about swastikas are reprints of earlier works. *The Swastika*, by Thomas Wilson (Washington: Smithsonian Institution, 1896), covers description, origin, and dispersion throughout the world and contains an extensive annotated bibliography and many illustrations. *The Migration of Symbols*, by Eugene F. Goblet D'Alviella (New York: Burt Franklin Publishers, 1972), devotes a chapter to the swastika, which discusses geographical distribution, interpretation of meaning, history of use, and origin (reprint of the 1894 edition). The first chapter of *The Migration of Symbols and Their Relations to Beliefs and Customs*, by Donald A. Mackenzie (New York: AMS Press, 1970), also deals with the meaning, distribution, and use of the swastika (reprint of the 1926 edition). Further background on Hindu astronomy and the nine planetary gods can be found in *A Historical View of the Hindu Astronomy from the Earliest Dawn of That Science in India to the Present Time*, by John Bentley (New York: International Publications Service, 1970), a reprint of an 1825 edition.

**Indian Fire Ecology** (p. 76)

*Fire and Ecosystems*, edited by T. T. Kozlowski and C. E. Ahlgren (New York: Academic Press, 1974), is a collection of papers on both harmful and beneficial effects of fire on a variety of soils, soil organisms, birds, mammals, and plants. A useful monograph available from Canada's Minister of Supply and Service is *The Effects of Fire on the Ecology of the Boreal Forest, with Particular Reference to the Canadian North: A Review and Selected Bibliography, Occasional Paper No. 32*, by John P. Kelsall, E. S. Telfer, and Thomas D. Wright (Ottowa: Canadian Wildlife Service, 1977). *Man's Role in Changing the Face of the Earth*, edited by W. L. Thomas (Chicago: University of Chicago Press, 1971), has a chapter, by Omer C. Stewart, on "Fire as the First Great Force Employed by Man."

*Katharine D'Agosta*

WHO SAYS YOU CAN'T SPEAK ANOTHER LANGUAGE...FAST!

With Linguaphone, you can speak a new language – fluently and idiomatically – in a relatively short time. It's an easy, interesting, natural method – used by leading schools and universities worldwide. You listen to and imitate flawless native speakers. No old-fashioned verb drills! Over 4,000,000 successful students. Record and cassette courses in more than 36 languages.

FREE RECORDED DEMONSTRATION!

Mail coupon today for your FREE demonstration recording and illustrated brochure. (The Linguaphone method is the same for *all* languages.) See how quickly, easily, you can learn a new language with Linguaphone!

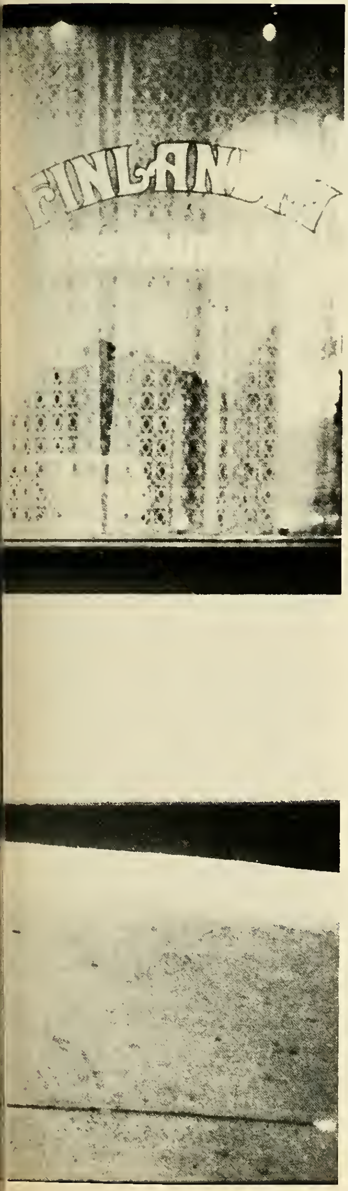
# Tasty Pasty

*In Michigan, a Cornish delicacy is given a Finnish flavor*

FINLANDIA
BAKERY

Photographs by Dan Seifert

by Raymond Sokolov



*The Finlandia Bakery caters to the tastes of the Upper Peninsula's Finnish population. Here local Finns can purchase sweet Finnish cardamom bread, as well as excellent Cornish pasties.*

Anyone who thinks that ethnicity in America is a simple matter should make a trip to the copper country of Michigan's Upper Peninsula. There are other reasons for visiting the area: grand stretches of unsullied northern woods, the oceanic expanse of Lake Superior, wild rivers like the Yellow Dog. But eventually the most ardent outdoorsman will stop for a sample of Superiorland's most typical local food, the pasty, a large half moon of short pastry filled with chopped meat and vegetables.

The pasty (pronounced pass-tee) is as much a feature of the Upper Peninsula landscape as the white pine. In 1968, sidestepping pressure to name it the state food, Gov. George Romney went so far as to declare May 24 Michigan Pasty Day. Madelyne's, the pasty world's equivalent of Stouffer's, passed the million-pasty mark years ago at its Ishpeming factory, and independent pasty shops punctuate the fir-lined highways. It was in such a place that I—then just a boy with boyish notions—first bit into a pasty. I stepped up to the counter and asked for a "pays-tee," only to realize from the smirk on the waitress's face that I had made a ludicrous error. The kind of pasty I had asked for was available only in shops specializing in the accouterments of what is politely termed exotic dancing. My other mistake was more sophisticated: I assumed I was eating a Finnish delicacy.

The copper country is a Finnish enclave. People with Finnish surnames abound, descendants of turn of the century immigrants who came to work the iron and copper mines or to clear the land and farm it. At Hancock, Finnish Lutherans established Suomi College. Suomi is the Finnish name for Finland; it is also the name of a small upper Michigan village. At one time, the Upper Peninsula was a hotbed of Finnish-language theater and newspapers, fraternal lodges and mutual aid societies. Much of this has vanished, but the Lutheran Church in Gwinn still holds a service in Finnish once a month. In 1976, Central Upper Peninsula Finnish-Americans united in a special bicentennial celebration. And in downtown Marquette, the Upper Peninsula's largest town (population 22,000), there is a restaurant and bakery called Finlandia.

When I first stopped there in the mid-seventies, the owner had a Finnish name and served Finnish specialties, such as the flat rye bread called *rieska*, as well as excellent pasties. Even today, when the new owner describes himself as "half-French, half-Polack," a sign on the wall thanks customers in Finnish (*kiitoksia*) and sells a sweet Finnish cardamom bread. There are still pasties, too, but they are no more Finnish than lasagne.

The Michigan pasty was long ago adopted by local Finns, but it came to the state with the Cornish miners who arrived about 1850. Their big hot pies were the ideal portable lunch: you could carry them in your pocket all morning, enjoying their warmth, and then you could eat them with your hands, holding them upright so that the juices drained to the bottom as you worked from one end to the other.

Although there is no real doubt in anyone's mind that the Cornish Cousin Jacks and Cousin Jennies (as Cornish people are known colloquially) were the original pasty makers in Michigan, the inquiring gastroethnographer can uncover earlier, more widespread sources for the dish. Pasties are mentioned in Middle English literature written outside Cornwall. Chaucer and Gower knew about pasties. Later on, Shakespeare's Mistress Page, in *The Merry Wives of Windsor*, offered a

PASTIES
FRESH DAILY

*The pasty was probably brought to Michigan by Cornish miners who were called Cousin Jacks and Jennies. This restaurant in Marquette acknowledges the pasty's origin.*

''hot venison-pasty'' to Falstaff. Neither Windsor nor the Globe Theater of Elizabethan London was a center of Cornish culture. Indeed, the word *pasty* obviously derives from the same Late Latin word for dough as such modern terms as *pasta, pâté*, and *pâte*, all of which have to do with moistened flour, paste. And even the idea of a free-standing meat pie surrounded by dough has been universal in Europe from the medieval period to modern times.

In Finland, for example, in the eastern district of Karelia especially, there are many kinds of small, filled pastries. In *The Finnish Cookbook*, Beatrice Ojakangas gives recipes for rye-flour pasties, sometimes baked, sometimes fried, with a slit in the middle. Some are stuffed with ground meat, some with carrots, some with salmon fillets, some with cabbage. The Finnish name for this family of stuffed pasties is *piirakkaa*, an obvious cognate of the Russian word for filled dumpling, *pirog*. Finland's border with Russia has swung back and forth over the centuries, and the food of Karelia is heavily Russified. But the Finnish culinary imagination has put its own stamp on the Karelian cuisine. No one can say with certainty if *piirakkaa* or *pirog* came first.

But just as the Cornish immigrants to Michigan considered *their* pasties to be theirs, the Finns must have thought that the filled pies they had learned to make in the old country belonged by inheritance and tradition to them. Yet, with the exception of a rarely seen, rye-crusted fish pie called *kalakukko*, the Finnish pasties of Finland do not seem to appear on the tables of Michigan Finns.

Latecomers to the shores of Lake Superior, the Finns found Cornish Cousin Jacks already well established in the mines. The Cornishmen had the advantage of speaking English (or at least a special version of it) from the start, and they were often foremen supervising Finns. Like other immigrant groups, the Finns rapidly adapted to the new culture they found in the Upper Peninsula. One of the lessons they learned was how to cook the locally well-entrenched Cornish meat pie.

Bertha Hill, for example, learned to make Cornish pasties from her mother, who was born in Finland. But she also learned regular Finnish dishes, such as the baked cheese, *juustoa*, and the oven ''pancake'' called *kropsua*. She grew up in a bicultural world, speaking English and Finnish, cooking in two styles. But in her lifetime, she has felt strong pressures at work undermining the strength of the Finnish component in her background. Her name, Hill, is a translation of a common Finnish surname, Maki. Her son, who learned to speak Finnish at home, was so mercilessly mocked at school that he dropped the language completely and simply refused to use it.

Today, Mrs. Hill runs the kitchen at a nearby country school and lives on an eighty-acre, former homestead farm, where she sometimes bakes in the oven of a white porcelain, old-fashioned Monarch wood-burning stove. Her pasties (see recipe) are better than any of the commercial pies I sampled on a recent trip to the Upper Peninsula, better even than the pasties at Kuz'n Jax in Marquette. This is partly the result of her skill as a baker and partly because all her ingredients—from the vegetables down to the ground meat and lard—are produced on her farm. But in praising Mrs. Hill's pasties, one runs up against the question of authenticity.

In the first place, can a Finn prepare proper Cornish pasties? One local Cornishman who ran a pasty contest disqualified his own wife because of her Finnish blood. This seems indefensible to me on many grounds and even smacks, in a genteel way, of the same anti-Finnish prejudice that has made "Finlander" a term of opprobrium in the Upper Peninsula. As with all traditional recipes, the pasty is a battleground of fiercely disputed culinary theories. Among themselves, the Cornish argue whether the dough should have suet or lard as a shortening, whether the filling should contain rutabaga, whether it is necessary to include pork in the chopped meat, and how coarsely or finely to chop that meat. Some folks pull the crust up from both sides and crimp it together at the top; others pull it over from one side. Some layer the ingredients; others mix them. The pasty controversy recently erupted in the pages of the *Upper Peninsula Sunday Times.* Steamy letters were written to the editor. One liberal Cornishman from Wyandotte, Michigan, a suburb of distant Detroit, plumped for pasty diversity and lamented the disappearance of Cornish culture. "The Cornish-American," he wrote, "has abandoned his folkways with unseemly haste. The only thing that survives in America of Cornish heritage is the pasty, that triumph of the Cornish culinary art, although even here much has been lost."

Perhaps. Nevertheless, the pasty has entered the mainstream of one American region, preserving something of the flavor of Cornwall even when adapted by Finnish hands. It is not clear, however, how much longer the Upper Peninsula pasty can hold its own against the recent, aggressive inroads of the fast food chains that bestride the highway into Marquette from the airport, but for the moment, to paraphrase a Cornish adage, the Devil seems to have kept out of the Upper Peninsula, "for fear of being made into a pasty."

*Raymond Sokolov is a free-lance writer whose special interest is the history and preparation of food.*

### Bertha Hill's Pasties

3 cups unbleached all-purpose flour
Salt
⅔ cup lard
½ cup suet, diced
1 medium onion, peeled and diced
3 medium potatoes, peeled and diced
3 carrots, peeled and diced
¾ lb. beef chuck, coarsely chopped
¼ lb. pork loin, coarsely chopped
Pepper
Butter

1. Sift flour together with 1½ teaspoons salt.
2. Cut lard and suet into flour-salt mixture with a pastry blender until well incorporated, so that dough has the texture of coarse meal.
3. Stir in just enough cold water (a little more than ½ cup) so that dough will pull together into a mass. Let rest for an hour, covered.
4. Preheat oven to 425 degrees.
5. Mix together the vegetables and meats to make the filling. Season to taste with salt and pepper. Moisten with ½ cup cold water.
6. Take one-fourth of the dough and roll it out on a lightly floured surface to a circle 9 to 10 inches in diameter. Trim the edges using an inverted plate as a template.
7. Fill the circle with a mound of one-quarter of the filling. Dot the filling with butter. Place the filling on one side of the dough and shape into a mound that extends across one semicircle.
8. Pull the uncovered semicircle of dough over the filling and press it down against the opposite edge. Fold the crimped edge of the dough over on itself and press closed with the fingers. The pasty should look like a bulging half moon.
9. Continue in this manner until you have four large pasties.
10. Bake on a greased cookie sheet. After ten minutes, reduce heat to 375 and continue baking another 50 minutes or until done. The pasties are cooked when a fork will press easily through the crust and into the potato pieces inside.

Yield: Four pasties

**X. Rousseau and Revolution.** Europe from the Seven Years' War to the storming of the Bastille.

**XI. The Age of Napoleon.** France's domination of European history, from the fevers of the French Revolution to Napoleon's defeat at Waterloo. A history of European civilization from 1789 to 1815.

## Will and Ariel Durant's masterpiece is now offered as your first benefit of membership in the Book-of-the-Month Club.®

The complete 11-volume set: **\$24⁹⁵**
Publisher's list price: \$241¹⁰

You simply agree to buy four books within a year.

SINCE the first volume of this remarkable work appeared forty-four years ago, it has been hailed both as a great literary achievement and an epic history of mankind. To read it is to enjoy the past made live with excitement and power. To own it is to have at your fingertips a reference work of undisputed authority. It is hard to imagine a more valuable set of books for your home library.

Beginning with this special opportunity to own *The Story of Civilization*, you'll enjoy continuing benefits on the best and most important books published today. Every Club book is as good as, or better than, those sold in stores. As a Club member, you select from the best and you *don't* settle for the altered or inferior editions that some book clubs send their members.

After a brief trial period, you'll also benefit from our Book-Dividend® system, which lets you save at least 70% on current art books, reference sets, literary classics, records, children's books and more.

Join Book-of-the-Month Club now, and shop for books the civilized way—in Americas Bookstore.®

### Facts About Membership

You receive the *Book-of-the-Month Club News*® 15 times a year (about every 3½ weeks). Each issue reviews a *Main Selection* plus scores of Alternates.

If you want the *Main Selection* do nothing. It will be shipped to you automatically. If you want one or more Alternate books—or no book at all—indicate your decision on the reply form always enclosed and return it by the date specified.

*Return Privilege:* If the *News* is delayed and you receive the *Main Selection* without having had 10 days to notify us, you may return it for credit at our expense.

*Cancellations:* Membership may be discontinued, by either you or the Club, at any time after you have purchased 4 additional books.

# The 80th-Anniversary Natural History Photographic Competition Is Open For Entries

To celebrate its eightieth year of publication, and to entice you to submit your best photographs, *Natural History* has put together a bountiful package of awards for the winners of this year's photographic competition.

The Grand Prize-winner of the 80th-Anniversary *Natural History* Photographic Competition will be invited to join the American Museum of Natural History's two-week cruise around Britain and Ireland in July. This $3,000-plus prize includes air fare from New York and accommodations on the luxury cruise ship *Orpheus*.

The itinerary includes London, Southampton, Dover, Edinburgh, the Shetland Islands, Loch Ewe, Galway, Holyhead, and Guernsey, with land excursions to Canterbury, Hadrian's Wall, Holy Cross, and spectacular natural settings.

Thomas D. Nicholson, director of the American Museum and astronomer, and six other scholars will introduce travelers to the archeological, historical, and natural treasures along the route.

The 80th-anniversary competition also will award seventeen cash prizes totaling $3,500. The winning entries will be published in the July issue of *Natural History* and exhibited at the American Museum of Natural History.

First prizes of $500 each will be awarded in three major categories: The Human Family; Animals (including birds and bugs); and Plants and Their Environment. Merit Awards of $250 each will go to the best entries in four categories: Photomicrography; A Sequence in Nature (up to five photographs); Urban Wildlife; and Humor in Nature. Ten Honorable Mentions of $100 each will be selected from all entries.

Competitors may submit up to five entries in the competition.

The deadline is April 1, 1980. Please put your name and address on every entry and include a stamped, self-addressed envelope—since we want to return your pictures to you.

And good luck!

## THE RULES

1. The competition is open to everyone except employees of the American Museum and their kin.
2. Competitors may submit up to five previously unpublished entries (a sequence is considered a single entry).
3. The Museum acquires the right to publish, exhibit, and use for promotion the winning photographs. The Museum assumes no responsibility for other entries.
4. Entries may be transparencies or prints, either color or black and white, up to 8 by 10 inches. Each must bear the photographer's name and address.
5. Enclose a self-addressed, stamped envelope for the return of entries.
6. Entries must be postmarked no later than April 1, 1980.

Pack them carefully and mail them to:

HEADPHONES
STEREO/FM AM RECEIVER STR-V55

# THE COMPANY THAT VIRTUALLY INVENTED TRANSISTORIZED HIGH FIDELITY HAS JUST REINVENTED THE RECEIVER.

For three decades the engineers at Sony have been behind not just one or two, but eighteen major technological innovations in high fidelity. One of our engineers even won a Nobel Prize.

The fact is, much of the hi-fi equipment made today is based on technology developed at the audio labs of Sony.

And now Sony introduces the new STR-V55. The receiver that, we assure you, will send the competition reeling back to their drawing boards. Especially when they note its list price.

### A COMPUTER FINDS YOUR STATION.

Unlike our competitors, we didn't just make a few improvements in an ordinary receiver and call it "new."

We actually reinvented it.

Instead of using the same basic tuning mechanism that's been found in radios since the days of Marconi, the new V55 uses microprocessor tuning to insure crisp, clear, perfect sound. We call this "quartz frequency synthesized tuning." It's totally computerized. So there are no strings, pulleys, flywheels, or other mechanical paraphernalia that can wear out and become less accurate as the years go by.

Equally innovative is a memory feature that lets you preselect up to eight AM or FM stations for instant push-button tuning. Use our exclusive "memory scan" device and you automatically hear 3.5 seconds of each. And there's a three-position muting level switch that enables you to hear only the stations you want to hear—and never the noise in between.

### PULSE POWER: ANOTHER SONY FIRST.

Even the most sophisticated ear would have quite a difficult time hearing any distortion in the new Sony V55 receiver. That's because, statistically, the V55 puts out 55 watts per channel from 20 to 20,000 hertz with less than 0.02% total harmonic distortion.

One of the reasons: an incredibly advanced. Sony developed "Pulse Power Supply." It not only completely eliminates any trace of audible distortion, but it's a fraction of the size and weight of conventional power supplies. So it doesn't require a forklift truck to carry it home from the store.

All this adds up to the elimination of hum and noise and, when combined with the V55's DC power configuration, delivers richer, cleaner bass response.

### ADVANCEMENTS, MORE ADVANCEMENTS AND STILL MORE ADVANCEMENTS.

Naturally, we could go on and on about such things as the V55's new transistor design which greatly extends the high-frequency range for more accurate sound reproduction.

Or about our switches that allow you to record automatically from one tape deck to another—without spending half your time rearranging wires.

Or about our special low filter device that lets you remove subsonic noise from your records without removing music.

Or about how the V55 is the one state-of-the-art receiver that won't require you to get a second mortgage to purchase it. And we at Sony confidently state it's by far the best investment you can make in hi-fi this year.

For more information on the complete line of new Sony receivers and the name of your nearest Sony dealer write: Sony, P.O. Box CN-04050, Trenton, New Jersey 08650.

**SONY AUDIO**

It's all you need to know about high fidelity.

FEATURES AND SPECIFICATIONS: 55 watts per channel with 0.02% distortion/Quartz freq. synthesis AM-FM/8 station memory IC (nonvolatile)/4 way tuning system/3 position tuning level/Pulse Power Supply/Hi-$f_T$ output transistors/M/C cartridge capability/Dual tape monitoring and dubbing controls/Subsonic Filter (15 Hz-12 dB per oct)/Gold-plated phono input.

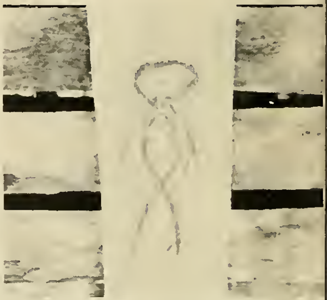
# Authors

**Mark Owens** was teaching at the University of Georgia when he met and married one of his students. After their marriage, Mark, who had a research background in glacial geology, and **Delia Owens** decided to go to Africa in search of a suitable research project. Their first choice was the teeming animal life of the Okavango Swamps in Botswana, but unusual rains made the area inaccessible. So they ventured into what seemed the next best choice: the Kalahari Desert. With a more than slightly used Land Rover, which cost them fifty dollars of their own precious funds, they crossed 125 miles of sand track and discovered a population of brown hyenas in the Deception Valley of the Central Kalahari Game Reserve. That was in 1974, and they have been studying hyena behavior and ecology ever since. Their isolation and experiences with the Land Rover have made them keenly interested in aviation.



**Edmund Carpenter** teaches anthropology at the New School for Social Research and communications at New York University. His accompanying portrait was painted by a Biami of Papua who saw him as a pale ancestor and rendered his likeness accordingly. An authority on the art and culture of the Arctic, but with a wide-ranging interest in other regions as well, Carpenter has lived and worked among Eskimo and Indian societies for many years. He is the author of *Eskimo Realities; Oh, What a Blow That Phantom Gave Me!* and several other books. His last article for *Natural History*, in May 1978, was "Silent Music and Invisible Art."

**Robert L. Smith** confesses he was "quite likely contemplating the biological and cultural consequences of feminist demands" when he first observed an egg-laden male water bug and instantly chose it as the subject for his doctoral dissertation in zoology from Arizona State University. He has subsequently traveled in Argentina, Mexico, and the United States to study these creatures and their paternal brooding behavior. As assistant professor of entomology at the University of Arizona, Smith has expanded his interest to include the behavior and ecology of urban insects but has been unable to shake his fascination with giant water bugs. He expects to continue to study them "for the duration."

# THE TASTE BEYOND 12-YEAR-OLD PREMIUM SCOTCH

Discover more.

Let your mature taste lead you from the finest premium Scotch on up to the most expensive 12-year-old Scotch in the world. The Glenlivet. The ultimate in Scotch.

Most premium Scotch is blended and depends on several whiskies for taste and smoothness.

Yet the unblended character of The Glenlivet is noble enough to stand alone. In this distinctive Scotch whisky you'll experience an exceptional smoothness and full-bodied richness, unmatched in all other premium Scotch.

Try the taste beyond premium Scotch.

"I have been intrigued by the skin-shedding behavior of snakes since I was about nine," writes **Leonard G. Appleby**. "I now study snakes almost exclusively and would describe myself as a compulsive ophiologist." A native of Surrey, England, where he makes his home in the village of Surbiton, he has studied the snakes of Great Britain for forty years. In addition to his continuing work on ecdysis and thermoregulation, he is investigating the ritualistic combat displays of male snakes. Appleby is something of a sculptor, using soft metals or wood as his medium. The subjects, of course, are snakes. He also reports that he enjoys "writing humorous prose in an inane vein, and nonsense verse that's even worse." Some of the former has been published.

# The 80th-Anniversary Natural History Photographic Competition Is Open For Entries

To celebrate its eightieth year of publication, and to entice you to submit your best photographs, *Natural History* has put together a bountiful package of awards for the winners of this year's photographic competition.

The Grand Prize-winner of the 80th-Anniversary *Natural History* Photographic Competition will be invited to join the American Museum of Natural History's two-week cruise around Britain and Ireland in July. This $3,000-plus prize includes air fare from New York and accommodations on the luxury cruise ship *Orpheus*.

The itinerary includes London, Southampton, Dover, Edinburgh, the Shetland Islands, Loch Ewe, Galway, Holyhead, and Guernsey, with land excursions to Canterbury, Hadrian's Wall, Holy Cross, and spectacular natural settings.

Thomas D. Nicholson, director of the American Museum and astronomer, and six other scholars will introduce travelers to the archeological, historical, and natural treasures along the route.

The 80th-anniversary competition also will award seventeen cash prizes totaling $3,500. The winning entries will be published in the July issue of *Natural History* and exhibited at the American Museum of Natural History.

First prizes of $500 each will be awarded in three major categories: The Human Family; Animals (including birds and bugs); and Plants and Their Environment. Merit Awards of $250 each will go to the best entries in four categories: Photomicrography; A Sequence in Nature (up to five photographs); Urban Wildlife; and Humor in Nature. Ten Honorable Mentions of $100 each will be selected from all entries.

Competitors may submit up to five entries in the competition.

The deadline is April 1, 1980. Please put your name and address on every entry and include a stamped, self-addressed envelope—since we want to return your pictures to you.

And good luck!

## THE RULES

1. The competition is open to everyone except employees of the American Museum and their kin.
2. Competitors may submit up to five previously unpublished entries (a sequence is considered a single entry).
3. The Museum acquires the right to publish, exhibit, and use for promotion the winning photographs. The Museum assumes no responsibility for other entries.
4. Entries may be transparencies or prints, either color or black and white, up to 8 by 10 inches. Each must bear the photographer's name and address.
5. Enclose a self-addressed, stamped envelope for the return of entries.
6. Entries must be postmarked no later than April 1, 1980.

Pack them carefully and mail them to:

If you have ever taken a luxury sports car through a tight turn, you know the feeling. It's the sense of supreme precision with which this trim, compact camera proclaims its Nikon heritage. A feeling that is borne out by the professional quality pictures the Nikon FE delivers with automatic ease. And one that, unlike other fine things in life, is readily affordable.

*With the Nikon FE,* you can simply focus and shoot... and rely on its Nikon electronics to give you sharp, magnificently exposed photographs, automatically. Or, switch to manual operation and enjoy complete creative control over every exposure, more easily than you ever thought possible.

*Above all,* this is a camera that makes no compromise in its supreme Nikon quality. Stroke the advance lever, and feel the smoothness of precision gearing machined to microscopic tolerances. Press the exposure button, and hear the shutter respond with hushed precision. Look through the bright, silver-coated viewfinder, and see your picture snap into sharp focus with a fingertip touch.

*Know, too,* that the world's greatest photographic system stands behind your Nikon FE. Add the dynamic firepower of motor drive, at up to 3.5 shots a second. Banish darkness with the ingenious automatic thyristor flash. Explore new perspectives through more than 60 Nikkor lenses, the same superb optics chosen by most professionals for their sharpness and color fidelity.

**For the purist:**
**The Nikon FM**
For those who prefer only manual exposure control, the Nikon FM offers the reliable guidance of one-step electronic metering. It's as compact and precisely responsive as the FE and costs even less. At your Nikon dealer.

# Turtles and the Revolution

General Anastasio Somoza-Debayle was not known for being a friend of the green turtle. His reputation had more to do with the way he ruled Nicaragua. But in 1977, even though he was reported to have an economic interest in the country's turtle business, he banned commercial-export turtling and closed the several processing plants operating in the country. His action was at least partly due to the urging of Bernard Nietschmann ("When the Turtle Collapses, the World Ends," June/July 1974), who flew to Nicaragua at Somoza's request in 1975 to talk about the plight of the fast-disappearing turtles.

In July of 1979, Somoza was deposed (he is now living in Paraguay) and Sandinista revolutionaries formed a new government. The turtles were not, of course, central to the revolution, and their fate under the new government was unclear until last fall, when a government representative announced that Nicaragua, although it was in financial trouble, would try to establish a marine sanctuary for the turtles if economic and technical assistance were forthcoming from the international community.

*"Postscripts" is a collection of reports on what's new with old* Natural History *articles.*

Butchering green turtles on beach, Nicaragua, 1971

Bernard Nietschmann

Nietschmann, who was at the conference where the announcement was made, thinks the aid will come. If it does, it will mean that the last large population of green sea turtles in the western Caribbean will be protected where it breeds, on the Tortuguero nesting beach in Costa Rica (made a national park in 1976), and in its feeding area, the rich marine pastures of sea grass off the eastern coast of Nicaragua.

But the turtles were only half of Nietschmann's story. He had become deeply involved with the Miskito Indians, who traditionally depended on the turtle for food. In the 1960s, when the first turtle-processing plants were set up in Nicaragua, the Miskito began their entry into a cash economy, hunting the turtles to sell. The turtles would have eventually disappeared if this increased hunting pressure had kept up, but stopping commercial turtling left the Miskito stranded partway through a cultural change. What provision a marine sanctuary would make for them, or for subsistence turtling, is not known, but their reaction to the 1977 closing of the plants was clear. As Nietschmann reports in his book *Caribbean Edge* (Bobbs-Merrill, 1979), the Miskito he was closest to wrote him in 1977, saying, "This is my word to you. The government put the turtle on control. It was one thing that you the one that do it. All your friends give you Hell. You get lots of cursing. Was sad."

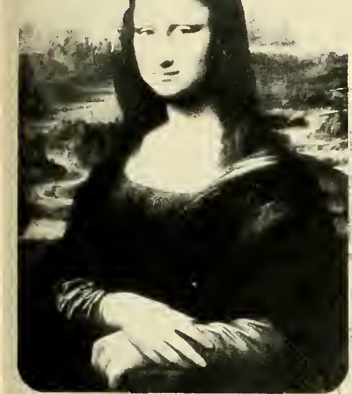
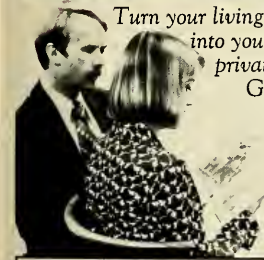
# 20 Color Slides of da Vinci Masterpieces for only $1 (comparable value $20)



LEONARDO DA VINCI

*Includes this Illustrated 40-page Gallery Lecture Guide*



*Turn your living room into your own private Art Gallery*

**HERE'S WHAT YOU GET FOR ONLY $1**

LEONARDO DA VINCI, a handsome Album with 20 beautiful color slides, including the beautiful and enigmatic "Mona Lisa" (shown above), radiant in her true colors and actual size . . . the tenderly evocative "Madonna and Child with St. Anne"..."St. John the Baptist"... "The Adoration of the Magi"... stunning details of the legendary "Last Supper"... and other priceless art treasures by Leonardo. The Album also contains an illustrated 40-page guided lecture by Renaissance authority Helmut Wohl, who gives you revealing background on the paintings and the enigmatic genius who created them.

RENOIR
REMBRANDT

## The Color Slide Program of the Great Masters

Come with us. To meet the legendary Leonardo. And share in the exciting discovery of the most celebrated masterpieces of all time.

Come to Paris, and behold the enigmatic smile which has fascinated men for centuries . . .

Visit Florence, and discover young Leonardo's first spark of brilliance in a painting that shamed a great teacher . . .

Travel to a refectory in Milan . . . to stand before the most unforgettable fresco in the world and sense the impending martyrdom of Christ.

LEONARDO DA VINCI--the complete Art Album with 20 full-color slides and handsomely illustrated Gallery Lecture Guide—is yours for only $1 as your introduction to the McGraw-Hill Color Slide Program of the Great Masters. There is no obligation to buy anything more.

### View the priceless works of art in the full glory of the originals

Each lavish Album contains twenty color slides devoted to the works of a famous master. Created by art photography specialists in Florence, Italy, these exquisite 35mm. slides achieve what small print and art reproductions cannot—for they capture the authentic colors of the original works . . . with every subtle line and detail brilliantly revealed. And they permit you to *view each priceless painting on your home screen in the full glory of the original.*

In addition, bound into each Album is an illustrated, 40-page Guide in which a noted authority points out important aspects of each painting and shares with you fascinating glimpses of the artist himself.

As you view the paintings projected on your wall and read the absorbing commentary, you and your family will discover a whole new dimension in the enjoyment of art. Indeed, it is much like taking your own "private tour" with an art expert at your side.

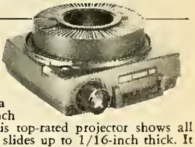
### The Program is flexible—the cost is low

Approximately every six weeks, you are offered a complete new Color Slide Album of 20 distinctive slides and an illustrated lecture. Forthcoming Albums will be devoted to the lives and works of such great masters as Michelangelo, Winslow Homer, Rembrandt, Gauguin, and Picasso, Chagall, Van Gogh, Lautrec, etc.

If the slides were available from museums, you would expect to pay as much as $20 a set. Yet, as a member of this new Program, you pay only $12.95 for each complete Album—including 20 color slides and 40-page illustrated lecture. And you may take as few or as many as you like.

### Accept this $1 demonstration offer

To introduce you to the McGraw-Hill Color Slide Program of the Great Masters, we will send you Leonardo da Vinci, complete, for 15 days trial. If you are delighted with the demonstration, send only $1, plus a few cents for tax and shipping. If not thrilled with the introductory Album, simply return it within 15 days; and you will be under no further obligation. Mail the attached card today.



If you do not have a projector: here's an unusual opportunity. We can offer you the sensational Kodak Carousel BC 604 Projector supplied with a 500-watt lamp, and 4-inch f/2.8 Ektanar lens. This top-rated projector shows all regular 2" x 2" 35mm. slides up to 1/16-inch thick. It has dependable gravity feed and you have instant access to any one of its 140-slide capacity at any time. List price $129.50—subscribers' price only $94.50, plus tax. Remittance must accompany trial subscription form. If you are not completely delighted with the projector, you may return it in 15 days for a full refund.

If Reply Card has been removed, write McGraw-Hill Color Slide Program of the Great Masters, Dept. AY-147, 1221 Ave. of the Americas, N.Y., N.Y. 10020.

## Feverish Lizards, and Crayfish, and Scorpions

Running a fever was once thought to be the prerogative of warmblooded creatures, whose internal temperatures are independent of the weather. But, as Matthew Kluger reported in "The Importance of Being Feverish" (January 1976), lizards can also develop fevers, even though there is no question that they are coldblooded. They raise their temperatures by moving into the sun or, in the case of Kluger's experiments, under a sun lamp. And it seems to do them some good. Sick lizards kept in cages at feverish temperatures fare much better than their counterparts in normal and cool environments.

Now, fever has spread to invertebrates. Recent studies have shown that crayfish and scorpions can develop fevers. Crayfish injected with bacteria and scorpions injected with prostaglandins swam and scuttled to hot areas. (Prostaglandins are hormones thought to be instrumental in the development of a fever.)

Evidence is also mounting that moderate fevers have their benefits, which might explain why the fever process is so widespread. Leukocytes, white blood cells that are active in fighting bacterial infections, are more mobile at febrile temperatures. And fevers reduce the amount of iron available to bacteria. That reduction, combined with high temperatures, has been shown to inhibit bacterial growth.

## Schistosomiasis, a Change in Strategy

In 1960, the word coming out of China was that schistosomiasis (snail fever) was under complete control and eradication was imminent. Almost twenty years later, in September of 1979, the *New York Times* offered the news that China had undertaken a vast, ambitious program to wipe out schistosomiasis by 1985.

Kenneth Warren, director of Health Sciences at the Rockefeller Foundation, was not surprised. Several years ago, in "Precarious Odyssey of an Unconquered Parasite" (May 1974), he set forth some of the reasons schistosomiasis, which affects 200 million people, resists efforts to eliminate it. Warren believes that such efforts, now being pursued in China, Brazil, and Egypt, are futile with current tools. He recently backed up his contention by designing, at Kenya's request, a program for control, not eradication, of schistosomiasis.

The difficulty with attempts at eradication is that they require striking the parasitic worm that causes schistosomiasis at every stage of its life. The worm, at different stages, lives in snails, humans, and in bodies of fresh water while it waits to infect one of its hosts. Eradication programs must include improving sanitation and protecting water supplies (eggs are excreted by infected human beings), killing snails, and killing the worms in human beings through medical treatment. So far there is no vaccine. Antischistosomal drugs are known for their toxicity to humans. And no molluscicides (snail-killing chemicals) have long-term, residual action. The problems are formidable even if one doesn't question the wisdom of killing large numbers of snails with chemicals.

Warren sees a way out of these difficulties in a significant characteristic of schistosomiasis: infection is not the same as disease. The worms do not multiply inside the human body; they produce eggs that are excreted. And individuals infected by a few worms may show no ill effects. Heavy infections, however, can cause a variety of disease symptoms and can sometimes be fatal. Another important characteristic of schistosomiasis is that schoolchildren have the highest incidence of infection.

Warren's recommended program, to cost $10 million over six years, would involve testing children ages five to nineteen in areas where schistosomiasis is endemic. Newly refined diagnostic procedures that allow quick tests in the field would be used, and only children with a certain level of infection would then be treated with drugs. Warren has devised a one-shot medication program that reduces the toxicity of the treatment by reducing the doses. He believes the program is a simple, economical alternative to eradication programs and that it will be effective in doing what can and should be done: treating the disease of schistosomiasis, not eliminating infection. The Kenyan government has not yet decided whether to go ahead with the program.

# New England Returns to Wood

*Faced with soaring energy costs and a disquieting dependence on foreign oil, this region has begun shifting to a former source of heat and power*

### by Colin High

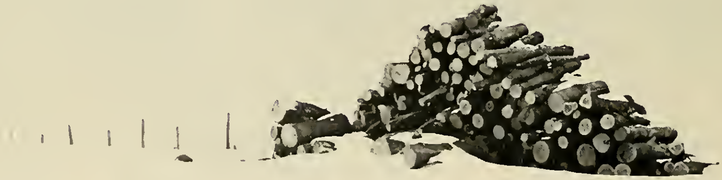
We are witnessing the rebirth of the use of New England forests, a trend that is growing so fast it is not yet reflected in most government statistics. Just as the bicentennial revived interest in the early history of the area, so rising fuel prices and supply problems have produced a renewed interest in the fuels of earlier times.

Although there are no statistics for those times, we are fairly certain that wood provided close to 100 percent of the fuel needs of the Pilgrim Fathers, as it undoubtedly also did for the American Indians before them. Wood continued to be the primary fuel for New Englanders until the latter part of the nineteenth century. It was used for heating homes, for cooking, and to produce the hot water needed on farms and for cottage industries. It provided charcoal for iron making and steam for the early steam engines, railroads, steamboats, and steam-powered sawmills. By 1850 there were thirty-six steam-powered sawmills fired by wood in Maine alone.

Along with water and wind, wood was the energy source for the American industrial revolution. In the second half of the nineteenth century, coal became increasingly important as an industrial fuel in the United States, although its use began relatively much later than in Europe, where the wood resource had been depleted much earlier. Not until the early 1870s did coal surpass the solar fuels—wood, water, and wind—as the primary industrial fuel.

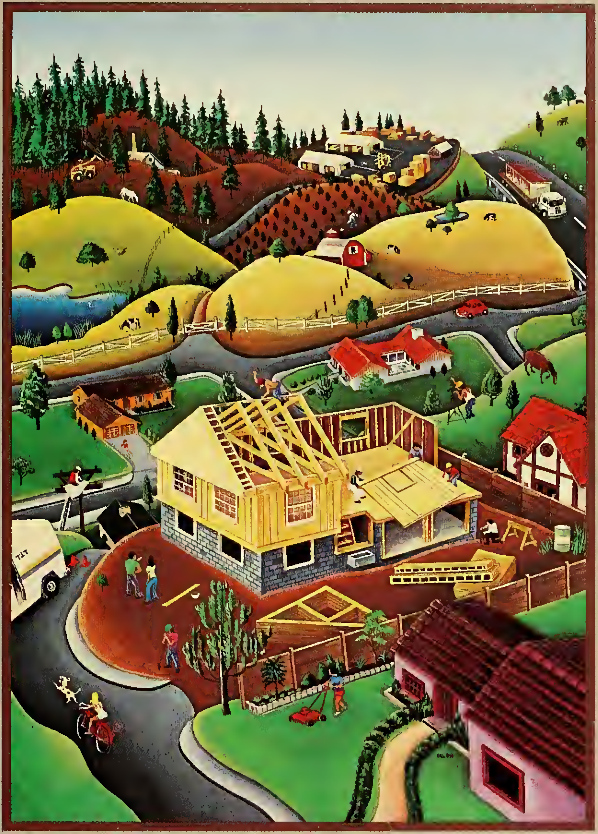
Until well into the twentieth century, wood remained the major home heating fuel in New England, finally declining only in the face of the abundance of cheap and convenient oil, gas, and electricity. By the time of the Arab oil embargo of 1973, the use of wood for home heating had declined to such a degree that even in Vermont, one of the most rural and wooded states in the nation, less than one percent of all homes used wood as the primary heat source.

The situation in the rest of rural New England was much the same, and in the urban areas, wood heating was relegated to the occasional use of the fireplace. Instead of relying on home-grown fuels, New England became dependent on oil, mainly imported from foreign sources. With the highest energy costs in the nation and the greatest dependence on foreign oil, however,



B.A. King

**What do you see when you look at a new house?**



A new neighbor? A good investment? Fallen trees? It depends on your point-of-view.

We see these things and more: an opportunity to meet society's need for shelter, our employees' for jobs and our shareholders' for performance.

So we manufacture houses, and parts of houses (things like lumber, plywood, cabinets and window frames); and we operate building materials centers through much of the U.S.

We also farm the trees that stand behind these products, and we're able to see clearly that society can have both, if we tend to our forests resourcefully.

So we strive to reconcile your viewpoints, to manage our affairs in a way that provides satisfactory jobs, products, profits and thriving trees.

If we succeed, everybody wins. Reason enough to try, don't you think?

**Boise Cascade Corporation**
A company worth looking at.

George A. Robinson

*The number of New Englanders heating their homes primarily with wood has increased from less than one percent to about 20 percent since the Arab oil embargo in 1973. Many homeowners now cut their own wood.*

the New England region is now looking to indigenous energy sources, especially renewable resources, to meet its future energy needs.

Change has begun and is taking two forms—conservation and a shift to wood. As a result, oil consumption may be 20 to 30 percent lower this winter than in the past. Although conservation is becoming a national phenomenon, the shift to wood for home and industrial heating is so far being led by New England. From less than one percent of homes heated primarily with wood prior to 1973, we now find 20 percent or more of homes in northern New England heated primarily with wood and more than 50 percent partly heated with wood. There are now enough fireplaces and stoves being installed to drive those numbers up very rapidly if home heating oil becomes scarce or much more expensive.

During the fall of 1979, the traditionally quiet, steady business of cutting wood for winter suddenly became feverish, with prices shooting up and waiting lists for deliveries of wood and chain saws. Homeowners discovered that the price differential between wood and oil was so large that even with the $300 to $500 or more spent on a stove, they could save hundreds of dollars in the first heating season.

If you are strong, like to be out in the woods, and have access to a pickup or trailer, you can go out and cut the wood yourself in rural areas. Even those who do not own woodlots frequently find neighbors who will allow dead and poor quality wood to be cut. Public forests also have opportunities for firewood cutters, and many large landowners and timber and paper companies permit local people to cut firewood free or at nominal cost. Perhaps half of all the wood now burned in New England homes is cut by the homeowner. Wood-cutting and wood-splitting parties are becoming popular as friends and neighbors turn to mutual aid instead of calling the oil company. Local businesses that sell wood stoves and chain saws, build chimneys, or rent hydraulic wood-splitters have been doing a roaring trade. On the other hand, local oil distributors have been having a hard time and some smaller, marginal companies may fail.

The resurgence of wood burning, however, has not been without its problems. Few people under forty or fifty years of age have had much direct experience of wood burning, and recent migrants from the cities, who often embrace wood heating with a religious fervor, have had no experience at all. Not surprisingly, there has been a spate of fires caused by ignorance and poor equipment or poor installation.

Burning wood is an art. You need to know your wood: the species, the condition, and the moisture content. A fast-burning, light softwood, such as pine, is fine for kindling, but to hold a good fire, you need oak, maple, or hickory. Apple holds a fire well all night and has a better aroma than anything out of a can or bottle. White birch looks beautiful in the grate of an open fire, but the serious stove user is not impressed by its heat value and tends to regard it as a city dweller's wood.

The experienced wood burner will use nothing but hardwood, except for kindling. Hardwoods generally have a much higher heating value per cord than softwoods. Perhaps just as important, they do not produce as much creosote or as many sparks as pine, spruce, or fir. Creosote is a big problem when heating a house all winter, especially a house with a modern, high-efficiency, "airtight" stove. As the hot gases driven off in the first stages of burning condense in the stovepipe and chimney, they build up and can catch fire. Burning the stove hotter with a good draft reduces creosote but makes it difficult to keep a fire going all night. Modern airtight wood stoves, so called because they have precise air regula-

# HOW DOES THE MAN WHO DRIVES THE SNOWPLOW DRIVE TO THE SNOWPLOW?

This one drives a Volkswagen Rabbit.

Now. We would love to tell you what a brilliant choice he made. How many different cars he checked out. How smart he was to choose a Rabbit.

But the fact is, he didn't have much of a choice at all.

A snowplow driver has two crucial needs:

1) Easy starts in the middle of winter.

2) Very good maneuverability in very bad weather.

Which means he needs both fuel injection for those starts and front-wheel drive for that maneuverability. Guess what?

With the exception of our own cars, there is only one car in the Rabbit's class that gives you both front-wheel drive and the option of fuel injection: the Rabbit itself. And with these features it's safe to say that only one car in this class combines the starting ease and maneuverability in snow like the Rabbit itself: the Rabbit itself.

Snowplow driver or not, we think you'll be impressed with the way the Rabbit is put together. With its performance, its handling, its carrying capacity.

Car and Driver was very impressed: "The Rabbit does more useful and rewarding things than any other small car in the world." Now the question is:

Does the man who drives the snowplow own a Rabbit to help him do his job?

Or does he do his job to help him own a Rabbit?.

ROCKY MOUNTAIN MASTERPIECE

The magnificent cougar, at home in the beauty of the Colorado Rockies, is captured by wildlife artist JAMES E. FAULKNER. When viewing this great work of art, it is easy to feel the crisp autumn air and hear the hypnotic rustling of the golden aspen. Now a special limited edition four color lithograph printed on heavy 100% rag paper.

THIS EDITION IS LIMITED TO ONLY 500 PRINTS EACH SIGNED AND NUMBERED BY THE ARTIST.

tors or thermostats, produce an even heat but they do not solve the creosote problem. The prudent stove owner checks the chimney regularly for creosote buildup and sweeps it often.

If there is an art to burning wood, there is an even greater art to cutting, splitting, and drying it. A few general principles will guide the neophyte, but only experience will make you an expert. Never cut wood shorter than you need for your stove (better buy a stove that takes long wood). Cut your wood in the fall: that is when the sap is lowest. Split it in the winter: frozen wood splits the most easily. Cut at least a year before you need to burn the wood: dry wood burns better than green wood. Wood cutting, splitting, drying, and burning are best practiced in time to the rhythm of the seasons. But there is an art to the splitting of wood, to the handling of mauls, wedges, and sledgehammers, to knowing which wood splits easily (straight ash or birch) and which will need a lot of work with wedges and hammers (elm and locust are notorious). My first wood-heated winter in New England cost me three splitting-maul handles for lack of experience in these arts.

Since it presents so many problems, why are so many people changing to heating with wood? For some it is a case of economic necessity. For the unemployed and those on low incomes who can cut their own wood, the savings, compared with oil, gas, or electricity, may amount to hundreds of dollars a year and make the long, cold New England winters bearable. But for those with little time to spare, cutting their own wood provides only a marginal return. And for people who buy their wood cut, split, and delivered to the home, costs range from about $75 to $120 per cord. At the top of this price range, wood is more expensive than oil at present prices, even if the wood is dry. When wood is burned green (moisture content 45 to 50 percent by weight), the heating value is only about 4,200 BTUs per pound compared to an average of 8,500 BTUs per pound for bone-dry wood. This means that someone burning green wood purchased for $75 per cord is probably not saving any money compared with buying home heating oil.

Nevertheless, many people are buying wood at $100 or more per cord. Clearly, something other than saving money must be motivating them. Throwing a log on a blazing fire obviously provides some satisfaction that

**Speak German like a Diplomat!**

What sort of people need to learn a foreign language as quickly and effectively as possible? Foreign Service personnel, that's who. Members of America's diplomatic corps are assigned to U.S. embassies abroad, where they must be able to converse fluently in every situation.

Now, you can learn to speak German just like these diplomatic personnel do—with the Foreign Service Institute's Programmed Introduction to German.

The U.S. Department of State has spent tens of thousands of dollars developing this course. It's by far the most effective way to learn German immediately.

The Programmed German Course consists of a series of tape cassettes and an accompanying textbook. You simply follow the spoken and written instructions, listening and repeating. The course begins entirely in English. But by its end, you'll find yourself learning and speaking entirely in German!

This course turns your cassette player into a "teaching machine." With its unique "programmed" learning method, you set your own pace—testing yourself, correcting errors, reinforcing accurate responses.

The FSI's Programmed German Course comes in two volumes. You may order one or both courses:

☐ Volume I, Basic.
9 cassettes, 13 hours and a 647-page text, $115

☐ Volume II, Advanced.
8 cassettes, 8½ hours and a 333-page text, $98.
(New York State residents add appropriate sales tax.)

Your cassettes are shipped to you in handsome library binders.

**TO ORDER, JUST CLIP THIS AD and mail with your name and address, and a check or money order.** Or, charge to your credit card (American Express, VISA, Master Charge, Diners Club) by enclosing card number, expiration date, and your signature.

**The Foreign Service Institute's German course is unconditionally guaranteed.** Try it for three weeks. If you're not convinced it's the fastest, easiest, most painless way to learn German, return it and we'll refund every penny you paid! Order today!

you do not get from hearing your furnace turn itself on. In these troubling times, that may be worth paying for. Having an alternative emergency fuel available also engenders a sense of security. There has long been a New England saying that wood warms you twice: once when you cut it and once when you burn it. Some people now add a third time: knowing you are not dependent on OPEC.

Although residential users are leading the shift from oil and electricity to wood, industrial users are also changing over. If homeowners are motivated by a mixture of economic and noneconomic reasons, industries have generally made the choice for economic reasons alone. Many of the industrial users who have switched from oil are in wood-products industries and burn the waste wood, sawdust, and bark they previously considered of little or no value. Starting with free or very low-cost fuel from waste, they have chalked up substantial savings in the first few years of operations.

There are 150 wood-burning industries in New England, from small sawmills and furniture factories to giant pulp and paper mills, which burn bark, wood, and wood-derived black liquor from the pulping process to generate steam and electric power. Some of these industries are powered almost entirely by wood, and some, like the Scott Paper Company's Somerset Mill in Maine, occasionally sell power to the electric grid. The Burlington Electric Department in Vermont retrofitted a coal-burning power plant to burn wood and now produces 7 megawatts of electric power for the city of Burlington. Although most of the industrial wood boilers depend primarily on low-cost wood wastes, the Burlington electric plant and a much smaller steam unit serving a hospital in Waterbury, Vermont, are examples of plants that burn wood harvested specifically for energy by whole-tree harvesting.

Unlike regular logging techniques, which normally use only the bole of the tree, whole-tree harvesting removes all the above-ground parts of the tree, which are then converted by machine into small chips. The chips are transported in large semitrailer vans, with twenty-ton loads, to an industrial boiler for burning. Whole-tree chipping has been used in New England and elsewhere to provide fiber for pulp mills and is expected to become the primary method for harvesting wood fuel for industrial use.

Discovery Tours

On such a scale, wood can be harvested and delivered up to fifty or more miles away at a cost of about $15 to $20 per ton ($36 to $48 per cord). At that price wood becomes competitive with oil even allowing for the increased capital investment and operation costs associated with wood burning. In view of this situation, the federal Department of Energy, state governments, and federally funded organizations, such as the New England Regional Commission and the Northeast Solar Energy Center, are encouraging industry to change from oil to wood in areas where wood is available.

In some areas it is possible that wood for energy may develop into the resource's major use. In northern Vermont, for example, just one proposed 50 megawatt, wood-fired power plant will, if built, double the wood harvest in the northern part of the state. If the domestic fuel wood market is added to this, wood used for energy may become an important factor in changing the forests of New England.

Proponents of wood energy can point to several important benefits that the growth of a large wood energy market could have in the New England forests. Wood as fuel could present the opportunity to market the large quantities of rough, rotten, and otherwise unmarketable trees that abound in New England's forests. From a production point of view, the present poor condition of the forests is the result of a long history of overexploitation of the high-quality trees, followed by a lack of forest management to regenerate high-productivity stands.

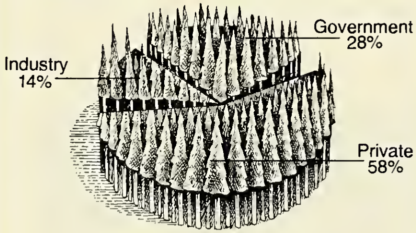
The lack of management occurred, in part, because it was difficult to make a decent return on the investment while large stands of old growth timber were available in the west and higher rates of growth could be obtained in the south. In addition, the land-ownership patterns of southern and central New England, which has many relatively small owners whose primary income comes from sources other than the land and whose reasons for holding the land are largely unrelated to forest production, have made good forest management more difficult. A wood energy market for the poor-quality material could provide the economic incentive to improve the stands by selective thinning and other management practices. Many foresters see the biggest benefit of wood energy as improvements to the timber stands, a policy they have long advocated but one that few landowners

A report on the great American forest.

# Good forest management means growing more trees. Not sharing shortages.

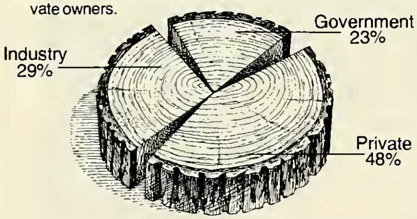
Who owns America's commercial forests?

Commercial forest acreage owned by the forest industry, government, and non-industrial private owners.



And how much do they produce?

Annual harvest from commercial forests owned by the forest industry, government, and non-industrial private owners.



Source: U.S. Forest Service

It's no accident that the most productive forests in America are those owned and managed by the forest industry.

Although they make up only 14% of the commercial forestland, they provide 29% of the annual timber harvest.

This is because the industry has learned that it's not only possible to grow more trees faster, but also imperative.

It's a race against time: Every year Americans need more lumber and plywood to build homes. More furniture to make them liveable. More paper and pulp to print the books and periodicals that educate, enlighten and entertain. More packaging and containers for thousands of essentials, from milk to machinery.

The sobering fact is that within 50 years U.S. demand for wood and paper products is expected to double.

Yet not all the nation's commercial forests are working equally hard to get ready.

## What is a commercial forest?

*Commercial forest,* as defined by the U.S. Forest Service, is *all* forestland — whether owned by individuals, government or the forest industry — that is capable of, and potentially available for, growing repeated crops of trees for harvest. It includes land in National Forests but not in National Parks or Wilderness areas.

On all commercial forestland, tree growth per acre averages only 61% of potential, which is not good enough. The greatest room for improvement, however, is in National Forests, where trees now grow at only 48% of potential.

Yet as the industry has shown, the growth cycle can be speeded by applying such techniques as: encouraging natural regrowth, planting superior seeds and seedlings, fertilizing, thinning and protecting trees from disease, insects and fire.

## How soon can we start growing more trees?

Since we clearly have the know-how to grow more and higher-quality trees, how soon can this nation get on with the job of increasing productivity on *all* commercial forestlands?

The first step is to understand the problem. If you'd like to learn more about the importance of America's forests and the challenges they face, send for a free booklet, "The Great American Forest." Write American Forest Institute, P.O. Box 873, Springfield, VA 22150.

The great American forest. Trees for tomorrow. And tomorrow. And all the tomorrows after that.

**Trees. America's renewable resource.**

could afford. Other benefits would be realized by loggers using whole-tree harvesting machines that increase productivity and reduce the job hazards associated with traditional logging.

Furthermore, whole-tree chipping reduces or eliminates the slash left after logging, which many landowners and recreational forest users find so objectionable. More open forests, with larger trees and a mosaic of cuttings, which could result from a well-managed, selective whole-tree harvest, would provide pleasant opportunities for recreational use and a diversity of habitats for wildlife.

Despite the advantages offered by large-scale, whole-tree, mechanized harvesting, there is no evidence that such a forest-management program will be adopted. At present, there are no laws or economic incentives to insure that it will take place. On the contrary, there may be short-term economic incentives that make it hard to practice good management. We know that wood fuel is, and probably will remain, the lowest-value wood product of the forests and that wood is competing closely with other energy sources. Loggers and landowners are therefore under constant pressure to keep costs down. To do so, loggers will have to make large investments in feller bunchers, skidders, and chippers to deliver fuel wood at a competitive price. A typical operation will need $500,000 for equipment, and loggers will have to be highly cost conscious and productive to make a return on the investment.

Large machines are undoubtedly more productive in clear cuts than in selective operations and that could lead to a substantial increase in clear-cutting. Clear-cutting may be right in some circumstances, but it has a far greater impact on the ecosystem than other cutting practices. All of the results traditionally associated with logging—increased runoff, soil erosion, water-quality problems, stream-temperature increase, nutrient removal, fish and wildlife disturbance, and adverse aesthetic and recreational effects—are more severe and difficult and expensive to manage in clear cuts.

There is one further problem with which we have relatively little experience, namely, the effect of whole-tree harvesting on soil nutrients and the long-term productivity of the forest. Although in most respects whole-tree harvesting produces the same results as traditional logging, it removes from the forest a much higher proportion of the biomass. The removal of small branches and leaves in whole-tree harvesting may be especially important because the leaves and twigs contain a disproportionately high concentration of plant nutrients—nutrients that might otherwise return to the soil in traditional harvesting. Moreover, we know that the decaying wood on the forest floor provides important sites for nitrogen fixation. To the extent that whole-tree harvesting reduces the amount of wood left to decay on the forest floor, it will reduce the rate of nitrogen return to the forest soil.

Although the impact on the nutrient budget of the forest may be quite small and may not affect forest productivity in the first rotation after whole-tree harvesting, there is a strong possibility that productivity will be affected after successive harvests employing whole-tree methods. If those methods were to be used only for the first harvest, the problem would be of less concern. But there is no reason to suppose that loggers will want to return to traditional methods in future harvests once they

B.A. King

*Commercially cut firewood ready for home delivery may not save the homeowner money at present. But as the costs of heating oil and electric rates continue to rise, wood is bound to become more and more economically attractive.*

**CUSTOMER INFORMATION FROM GENERAL MOTORS**

# HOW TO SAVE YOUR LIFE AND THE ONE NEXT TO YOU

**OVERCOMING YOUR PSYCHOLOGICAL RESISTANCE TO SEAT BELTS MAY BE THE KEY.**

The facts are startling. Experts estimate that about half of all automobile occupant fatalities last year might have been avoided if the people had been wearing seat belts. That's because injuries occur when the car stops abruptly and the occupants are thrown against the car's interior. Belts prevent this.

Many people say they know the facts, but they still don't wear belts. Their reasons range all over the lot: seat belts are troublesome to put on, they are uncomfortable, or they wrinkle your clothes. Some people even think getting hurt or killed in a car accident is a question of fate; and therefore, seat belts don't matter.

If you're one of those people who don't use belts for one reason or another, please think carefully about your motivations. Are your objections to seat belts based on the facts or on rationalizations?

**Here are a few of the common rationalizations.** Many people say they are afraid of being trapped in a car by a seat belt. In fact, in the vast majority of cases, seat belts protect passengers from severe injuries, allowing them to escape more quickly. Another popular rationalization: you'll be saved by being thrown clear of the car. Here again, research has proved that to be untrue—you are almost always safer inside the car.

Some people use seat belts for highway driving, but rationalize it's not worth the trouble to buckle up for short trips. The numbers tell a different story: 80% of all automobile accidents causing injury or death involve cars traveling under 40 miles per hour. And three quarters of all collisions happen less than 25 miles from the driver's home.

**When you're the driver, you have the psychological authority to convince all of the passengers that they should wear seat belts.** It has been shown that in a car, the driver is considered to be an authority figure. A simple reminder from you may help save someone's life. And please remember children can be severely injured in automobile accidents, too. Make sure Child Restraint Systems are used for children who aren't old enough to use regular seat belts.

Because so many people still don't use their seat belts, the government has directed that some form of passive restraint—one that doesn't require any action by the occupant—be built into every car by the 1984 model year. GM is offering one such restraint—a new type of automatic belt—as an option on the 1980 Chevette to gain insight into its public acceptance.

By the 1982 model year, we must begin putting passive restraints in all full-size cars and, eventually, into the entire fleet. But until you purchase one of these cars of the future, you can protect yourself and others by using seat belts and urging your family and friends to follow your example.

At GM, we're very concerned about safety. So please fasten your seat belt, because even the best driver in the world can't predict what another driver will do.

THE EDITION IS NEARING COMPLETION

This magnificent replica of Remington's THE OUTLAW cast in imperishable bronze in a limited edition of 1000

Frederic Remington is perhaps the best known artist-chronicler of the Old West. Late in his career, he created 23 dynamic bronzes. *The Outlaw*, which he completed a few years before his death, is considered one of his finest works. *The Outlaw*, originally cast in 1906, has become a rare collector's item. Any one of the 40 or more originals is now appraised at $135,000.

THE SECOND IN A COLLECTION OF LIMITED EDITION BRONZE REMINGTON REPLICAS

This limited edition replica is the second in a group of Remington bronzes specially commissioned by Museum Collections Inc., and issued in cooperation with the Buffalo Bill Historical Center, Cody, Wyoming. The first, *The Bronco Buster*, was fully subscribed and there is a waiting list of buyers.

Your purchase of this fine bronze will be registered in the archives of the Buffalo Bill Historical Center, and a Certificate of Ownership signed by the director of The Historical Center will accompany each sculpture.

*The Outlaw, by Frederick Remington. Actual size 17¼" with American walnut base. Cast in bronze by the lost wax process.*

SO FAITHFUL TO THE ORIGINAL THAT IT HAS BEEN SCALED DOWN TO AVOID CONFUSION

Every detail of Remington's original has been recreated in the replica—but it has been reduced one fourth in scale, foundry marked and dated, so that it may never be mistaken for one of the originals. This copyrighted edition is being cast under the auspices of Museum Collections Inc., using the lost wax process and patination that was used for Remington's original bronzes.

*The Outlaw, a front view.*

You are advised to order now. The final bronzes are being cast—then the molds will be destroyed.

To own the *The Outlaw* is to own an authentic classic of Western Art. Each bronze is individually hand-finished. Collectors have already reserved the major share of this fine edition. We therefore urge you to place your order for your bronze now, to avoid disappointment.

To order, call toll free...

*1-800-243-4492, or write: Richard Walker, President, Museum Collections Inc., Dept. NO2 Box 7000, Greenwich, Conn. 06830, for illustrated brochure.*

*Issue price, $1,250. You may reserve the next available numbered bronze immediately by sending us your check now. Major credit cards honored. A five-month payment plan may be arranged. We urge you to take prompt action.*

**Guaranteed re-purchase agreement:** Museum Collections Inc. will willingly re-purchase your numbered bronze of *The Outlaw* anytime within one year of your date of purchase. Thus, your investment in this bronze is fully protected.

*A Time Inc. Company*

have discovered the economic advantages of whole-tree methods.

Indeed, the improving technology for the production of composite wood products suggests that the market for wood chips to be used in the manufacture of wood products may also increase in the future. It has been suggested that "energy plantations" of fast-growing trees, harvested on short rotations with whole-tree harvesting methods, would be the way to produce wood fuel quickly and cheaply. If put into practice, this would be more like agricultural crop production than forestry as we know it and might cause soil erosion and water-quality problems that would parallel the seriousness of those in agriculture. But with or without energy plantations, whole-tree harvesting is here to stay.

Just as increased harvesting of wood for energy will pose difficult environmental management problems in the forest, increased wood burning in the home and industrial plants will give rise to air-pollution problems. Because wood is a renewable resource and wood smoke brings back pleasant memories of evenings around the campfire, a popular misconception has grown up that wood burning is totally benign. The problems of wood as fuel may cause less alarm than the health risks associated with coal or nuclear fuels, but wood is certainly not without some hazards.

Wood burning produces a wide range of emission products, some of which can present a health threat. The emissions include particulates, nitrogen oxides, carbon monoxide, hydrocarbons, and sulfur dioxide. The sulfur emissions are very low when compared with those of coal and most oils, and that makes wood a preferred fuel where sulfur dioxide pollution is a problem. On the other hand, particulate emissions, particularly where no control equipment is used, are higher than those caused by oil, being comparable to emissions from coal burning.

Fortunately, particulate emissions are relatively easy to control in industrial boilers and the control technology is widely available. Particulate emissions from residential fireplaces, stoves, and furnaces, however, are not controlled and these emissions are a cause for concern where there is a heavy concentration of home wood users. Many small towns in valleys where temperature inversions occur on cold winter nights are already beginning to experience noticeable air-

pollution problems from home wood stoves.

Hydrocarbon emissions are an additional cause for concern because the organic compounds present in wood smoke are suspected of being carcinogenic. When wood stoves are run closed for long periods, the pollution problem, like the creosote problem, increases and the amount of organic matter released under those circumstances can be much higher than normal. Emissions from home wood burning are completely unregulated at present and any attempted regulation is likely to be resisted by homeowners who have changed to wood.

As can be seen, the wood-energy market involves a number of tradeoffs. On one hand, if properly managed, it might provide a way in which the present poor-quality, low-productivity forest could produce more high-value timber and fiber while maintaining or improving environmental quality. Such management would need to forego short-term profit for longer-term profit. On the other hand, to supply the energy market at the lowest possible price, loggers and landowners might opt for maximum productivity in the short term, which would probably lead to increased clear-cutting and negative effects on the forest ecosystem and downstream water quality.

The problems of management are better understood now than they once were and there is a will on the part of most parties to consider environmental issues and long-term productivity. Nevertheless, the history of the exploitation of New England's forests has largely been a story of maximizing short-term profit at the expense of long-term benefits. That may be changing but a mechanism for insuring management for longer-term benefits has not yet emerged.

Forests provide not only fuel but also materials that can play an important role in conserving energy in manufacturing processes. Wood products use less energy than industrial substitutes, such as plastics, steel, and aluminum. We may hope that in the rush to get energy out of the woods to satisfy an appetite developed on an abundance of cheap oil we do not forget the multitude of other benefits that well-managed forests can provide.

Wilbur Streech's *The Path*, original serigraph. Signed limited edition of 250.

# In the Midst of Life . . .

*What would an algal mat think of the fiery finale of our solar system?*

Great storytellers often insert bits of humor to relieve the pace of intense drama. Thus, the gravediggers of *Hamlet* or the courtiers Ping, Pong, and Pang of Puccini's *Turandot* prepare us for torture and death to follow. Sometimes, however, episodes that now inspire smiles or laughter were not so designed; the passage of time has obliterated their context and invested the words themselves with an unintended humor in our altered world. Such a passage appears in the midst of geology's most celebrated and serious document—Charles Lyell's *Principles of Geology*, published in three volumes between 1830 and 1833. In it, Lyell argues that the great beasts of yore will return to grace our earth anew:

> Then might those genera of animals return, of which the memorials are preserved in the ancient rocks of our continents. The huge iguanodon might reappear in the woods, and the ichthyosaur in the sea, while the pterodactyl might flit again through the umbrageous groves of tree-ferns.

Lyell's choice of image is striking, but his argument is essential to the major theme of his great work. Lyell wrote the *Principles* to advance his concept of uniformity, his belief that the earth, after "settling down" from the effects of its initial formation, had stayed pretty much the same—no global catastrophes, no steady progress toward any higher state.

The extinction of dinosaurs seemed to pose a challenge to Lyell's uniformity. Had they not, after all, been replaced by superior mammals? And didn't this indicate that life's history had a direction? Lyell responded that the replacement of dinosaurs by mammals was part of a grand, recurring cycle—the "great year"—not a step up the ladder of perfection. Climates cycle and life matches climates. Thus, when the summer of the great year came round again, the coldblooded reptiles would reappear to rule once more.

And yet, for all the fervor of his uniformitarian conviction, Lyell did allow one rather important exception to his vision of an earth marching resolutely in place—the origin of *Homo sapiens* at the latest instant of geologic time. Our arrival, he argued, must be viewed as a discontinuity in the history of our planet: "To pretend that such a step, or rather leap, can be part of a regular series of changes in the animal world, is to strain analogy beyond all reasonable bounds."

To be sure, Lyell tried to soften the blow he had administered to his own system. He argued that the discontinuity reflected an event in the moral sphere alone—an addition to another realm, not a disruption of the continuing steady-state of the purely material world. The human body, after all, could not be viewed as a Rolls Royce among mammals:

> When it is said that the human race is of far higher dignity than were any preexisting beings on the earth, it is the intellectual and moral attributes only of our race, not the animal, which are considered; and it is by no means clear, that the organization of man is such as would confer a decided preeminence upon him, if, in place of his reasoning powers, he was merely provided with such instincts as are possessed by the lower animals.

Nonetheless, Lyell's argument is a

premier example of an all too common tendency among natural historians—the erection of a picket fence around their own species. The fence sports a sign: So Far, but No Farther. Again and again, we encounter sweeping visions, encompassing everything from the primordial dust cloud to the chimpanzee. Then, at the very threshold of a comprehensive system, traditional pride and prejudice intervene to secure an exceptional status for one peculiar primate.

I discussed another example of the same failure in last month's column—Alfred Russel Wallace's argument for the special creation of human intelligence, the only imposition by divine power upon an organic world constructed entirely by natural selection. The specific form of the argument varies, but its intent is ever the same—to separate man from nature. Below its main sign, Lyell's fence proclaims, The Moral Order Begins Here; Wallace's reads, Natural Selection No Longer at Work.

Darwin, on the other hand, extended his revolution in thought consistently throughout the entire animal kingdom. Moreover, he explicitly advanced it into the most sensitive areas of human life. Evolution of the human body was upsetting enough, but at least it left the mind potentially inviolate. But Darwin went on. He wrote an entire book to assert that the most refined expressions of human emotion had an animal origin. And if feelings had evolved, could thoughts be far behind?

The picket fence around *Homo sapiens* rests on several supports, but the most important pillars embody claims for *preparation* and *transcendence*. Humans have not only transcended the ordinary forces of nature, but all that came before was, in some important sense, a preparation for our eventual appearance. Of these two arguments, I regard preparation as by far the more dubious and more expressive of embedded prejudices that we should strive to shed.

Transcendence, in modern guise, states that the history of our peculiar species has been directed by processes that had not operated before on earth. As I argued in my recent column on Lamarck (October 1979), cultural evolution is our primary innovation. It works by the transmission of skills, knowledge, and behavior through learning—a cultural inheritance of acquired characters. This nonbiological process operates in the rapid Lamarck-

## No obligation to buy any future offerings.

This remarkable $2.98 offer is brought to you by The International Preview Society — a highly selective music program that does not oblige you to buy at any time. These multi-record/cassette selections — and many, many more superb choices will continue to be offered in an exclusive Preview magazine approximately every eight weeks. Each issue highlights a Featured Selection . . . plus an impressive variety of alternate selections (many available on cassettes). And all are well below suggested retail!

You'll save even more through *the Society's Half-Price Bonus Plan*. For every regular member purchase you make, you may choose a Bonus — album or multi-record set — for only *half* of the members' already low club price. *That amounts to a savings of more than 55% off the suggested retail price!*

If you'd like to preview the Featured Selection, you need do nothing. We'll send it automatically. But if you'd prefer an alternate selection or none at all, just mail back the Preview Notification card — enclosed with the magazine — by the specified date. You'll have plenty of advance notice.

**Audition Any Selection At Home For Ten Days . . . Free.**

At no cost or obligation, you are invited to audition any one of these multi-record albums . . . as well as any future offerings . . . at home for ten days. Only then do you decide whether or not to buy.

**As Many As Four Records For Less Than The Price Of One.**

You may choose any one of these sets for just $2.98 plus a small postage/handling charge. (Sales tax added for New York residents.) Remember, each set contains either three or four records (or 2 to 4 cassettes). That's a savings of as much as $36.94 . . . up to 92% off the suggested list price!

Send no money. We want you to judge for yourself before you decide to buy. If you are not delighted after ten days, return the set.

These are superior, silent-surfaced recordings by Deutsche Grammophon and Philips. They come in a handsome hinged storage case with an informative, illustrated brochure.

Every recording offered by the Society must meet the rigid standards of The Carnegie Hall Selection Committee. Only albums of the most exceptional musical interest, artistic excellence and technical quality are offered.

So do take advantage of this marvelous value and mail in the coupon today. You'll also be reserving the privilege of previewing other great international releases . . . which you may add to your collection at impressive savings.

ian mode, while biological change must plod along by Darwinian steps, glacially slow in comparison. I do not regard this unleashing of Lamarckian processes as a transcendence in the usual sense of overcoming. Biological evolution is neither canceled nor outmaneuvered. It continues as before and it constrains patterns of culture, but it is too slow to have much impact on the frenetic pace of our changing civilizations.

Preparation, on the other hand, is hubris of a much deeper kind. Transcendence does not compel us to view 4 billion years of antecedent history as any foreshadowing of our special skills. We may be here by unpredictable good fortune and still embody something new and powerful. But preparation leads us to trace the germ of our later arrival into all previous ages of an immensely long and complicated history. For a species that has been on earth for about 1/100,000 of the planet's existence (50,000 of nearly 5 billion years), this is unwarranted self-inflation of the highest order.

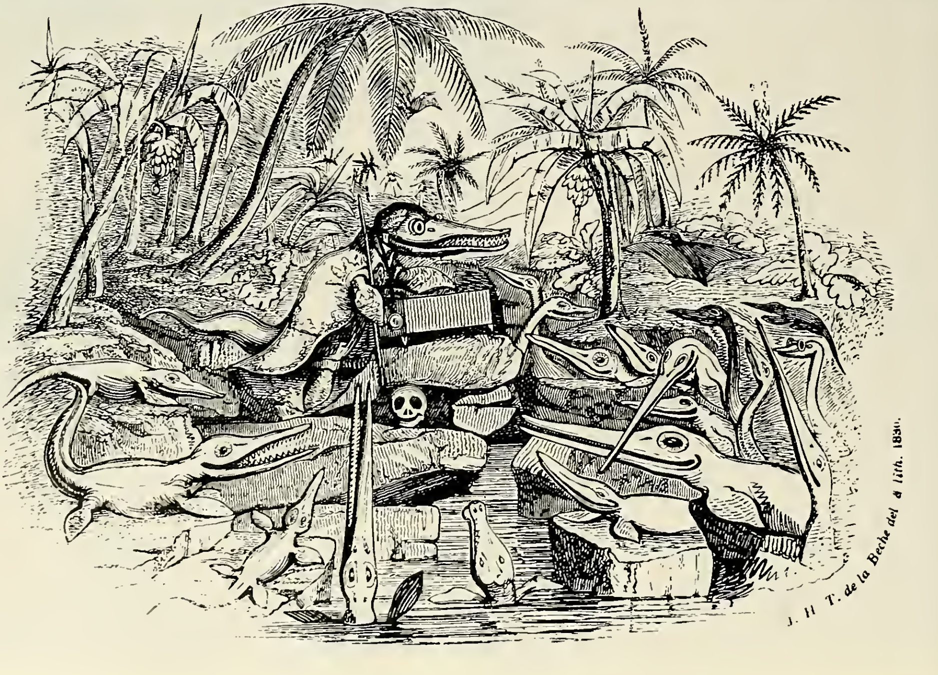
Lyell and Wallace both preached a form of preparation; virtually all builders of picket fences have done so. Lyell depicted an earth in steady-state waiting, indeed almost yearning, for the arrival of a conscious being that could understand and appreciate its sublime and uniform design. Wallace, who later turned to spiritualism, advanced the more common claim that physical evolution had occurred in order, ultimately, to link preexisting mind with a body capable of using it:

> We, who accept the existence of a spiritual world, can look upon the universe as a grand consistent whole adapted in all its parts to the development of spiritual beings capable of indefinite life and perfectibility. To us, the whole purpose, the only *raison d'être* of the world—with all its complexities of physical structure, with its grand geological progress, the slow evolution of the vegetable and animal kingdoms, and the ultimate appearance of man—was the development of the human spirit in association with the human body.

I think that all evolutionists would now reject Wallace's version of the argument for preparation—the foreordination of man in the literal sense. But can there be a legitimate and modern form of the general claim? I believe that such an argument can be constructed, and I also believe that it is the wrong way to view the history of life.

The modern version chucks foreordination in favor of predictability. It abandons the idea that the germ of *Homo sapiens* lay embedded in the primordial bacterium or that some spiritual force superintended organic evolution, waiting to infuse mind into the first body worthy of receiving it. Instead, it holds that the fully natural process of organic evolution follows certain paths because its primary agent, natural selection, constructs ever more successful designs that prevail in competition against earlier models. The pathways of improvement are rigidly limited by the nature of building materials and the earth's environment. There are only a few ways—perhaps only one—to construct a good flyer, swimmer, or runner. If we could go back to that primordial bacterium and start the process again, evolution would follow roughly the same path. Evolution is more like turning a ratchet than casting water on a broad and uniform slope. It proceeds in a kind of lockstep; each stage raises the process one step up, and each is a necessary prelude to the next.

Since life began in microscopic



J. H. T. de la Beche del & lith. 1830.

*In Lyell's own day, a colleague drew this satirical cartoon of a future Professor Ichthyosaurus lecturing his students about a curious skull from a previous creation.*

# REDUCE YOUR '79 TAX BITE.

## GET AN 8% IRA BEFORE APRIL 15.

A Manufacturers Hanover Individual Retirement Account (IRA) is a retirement plan which, if you are eligible, gives you tax benefits now, as well as retirement benefits later. You have until April 15, 1980 to deposit 15% of your earned income up to a maximum of $1,500 ($1,750 if you can contribute for a non-wage-earning spouse) and still deduct it on your 1979 tax return. You pay no tax on the principal or interest until the money is withdrawn. By then you should be retired with both a lower income and a lower tax bracket.

If you're an employee not presently covered by a qualified pension or profit-sharing plan, you could be eligible for an IRA from MHT. To get your Manufacturers Hanover IRA, just stop in at any of our more than 200 branches and make an initial minimum deposit of $400 into our 6-year Time Deposit Account.

The accompanying chart shows you the possibilities if you start making contributions now. We'll explain IRA's in full. And you may end up with a tax return that you can sink your teeth into.

HERE'S WHAT YOU'LL HAVE AT AGE 65, BASED ON A SINGLE ANNUAL CONTRIBUTION AT AN INTEREST RATE OF 8% IF YOU:

| Start Saving at Age | Put in Maximum of $1,500/Yr. | Start Saving at Age | Put in Maximum of $1,500/Yr. |
|---|---|---|---|
| 30 | $309,844.78 | 45 | $78,242.53 |
| 35 | $200,134.79 | 50 | $45,740.29 |
| 40 | $126,998.10 | 55 | $24,073.11 |

NOTE: In order to earn interest at this rate, deposits, including accrued interest, must not be withdrawn prior to maturity. Federal law and regulation prohibit the payment of an IRA Time Deposit (8% IRA) prior to maturity or before the depositor attains age 59½ (except in the case of death or disability), unless six months of the interest thereon is forfeited.

**MANUFACTURERS HANOVER**

It's banking the way you want it to be.

Member FDIC.

chemistry and has now reached consciousness, the ratchet contains a long sequence of steps. These steps may not be ''preparations'' in the old sense of foreordination, but they are both predictable and necessary stages in an unsurprising sequence. In an important sense, they prepare the way for human evolution. We are here for a reason after all even though that reason lies in the mechanics of engineering rather than in the volition of a deity.

But if evolution proceeded as a lockstep, then the fossil record should display a pattern of gradual and sequential advance in organization. It does not, and I regard this failure as the most telling argument against an evolutionary ratchet. Life arose soon after the earth itself formed; it then plateaued for as long as 3 billion years—perhaps five-sixths of its total history. Throughout this vast period, life remained on the prokaryotic level—bacterial and blue-green algal cells without the internal structures (nucleus, mitochondria, and others) that make sex and complex metabolism possible. For perhaps 3 billion years, the highest form of life was an algal mat—thin layers of prokaryotic algae that trap and bind sediment. Then, about 600 million years ago, virtually all the major designs of animal life appeared in the fossil record within a few million years. We do not know why the ''Cambrian explosion'' occurred when it did, but we have no reason to think that it had to happen then or had to happen at all.

Some scientists have argued that low oxygen levels had prevented a previous evolution of complex animal life. If this were true, the ratchet might still work. The stage remained set for 3 billion years. The screw had to turn in a certain way, but it needed oxygen and had to wait until prokaryotic photosynthesizers gradually supplied the precious gas that the earth's original atmosphere had lacked. Indeed, oxygen was probably rare or absent in the earth's original atmosphere, but it now appears that large amounts had been generated by photosynthesis more than a billion years before the Cambrian explosion.

Thus, we have no reason to regard the Cambrian explosion as more than a ''fortunate'' event that need not have occurred, either at all or in the way it did. It may have been a consequence of the evolution of the eukaryotic (nucleate) cell from a symbiotic association of prokaryotic organisms within a single membrane. It may have occurred because the eukaryotic cell could evolve efficient sexual reproduction, and sex distributes and rearranges the genetic variability that Darwinian processes require. But the crucial point is this: if the Cambrian explosion could have occurred any time during more than a billion years before the actual event—that is, for about twice the amount of time that life has spent evolving since then—a ratchet scarcely seems to be an appropriate metaphor for life's history.

If we must deal in metaphors, I prefer a very broad, low, and uniform slope. Water drops randomly at the top and usually dries before flowing anywhere. Occasionally, it works its way downslope and carves a valley to channel future flows. These myriad valleys could have arisen anywhere on the landscape. Their current positions are accidental. If we could repeat the experiment, we might obtain no valleys at all or a completely different system. Yet we now stand at the shoreline contemplating the fine spacing of valleys and their even contact with the sea. How easy it is to be misled and to assume that no other landscape could possibly have arisen.

I confess that the metaphor of the landscape contains one weak borrowing from its rival, the ratchet. The initial slope does impart a preferred direction to the water dropping on top—even though almost all drops dry before flowing and can flow, when they do, along millions of paths. Doesn't the initial slope imply weak predictability? Perhaps the realm of consciousness occupies such a long stretch of shoreline that some valley would have to reach it eventually.

But here we come upon another constraint, the one that prompted this column (although I have been, I confess, a long time in getting to it). Almost all drops dry. It took 3 billion years for any substantial valley to form on the earth's initial slope. It might have taken 6 billion or 12 or 20 for all we know. If the earth were eternal, we might speak of inevitability. But it is not.

Astrophysicist William A. Fowler argues that the sun will exhaust its central hydrogen fuel after 10 to 12 billion years of life. It will then explode and transform to a red giant so large that it will extend past the orbit of Jupiter, thus swallowing the earth. It is an arresting thought—the kind that makes you stop and contemplate or that sends shivers up and down your spine—to recognize that humans have appeared on earth at just about the halfway point of our planet's existence. If the metaphor of the landscape is valid, with all its randomness and unpredictability, then I think we must conclude that the earth need never have evolved its complex life.

It took 3 billion years to go beyond the algal mat. It might as well have taken five times as long, if only the earth had endured. In other words, if we could run the experiment again, the most spectacular event in the history of our solar system, the explosive exhaustion of its parent, might just as well have had an algal mat as its highest, mute witness.

Alfred Russel Wallace also contemplated the eventual destruction of life on earth (in his day, physicists argued that the sun would simply burn out and the earth freeze solid). And he could not accept it. He wrote of

> the crushing mental burthen imposed upon those who . . . are compelled to suppose that all the slow growths of our race struggling towards a higher life, all the agony of mârtyrs, all the groans of victims, all the evil and misery and undeserved suffering of the ages, all the struggles for freedom, all the efforts towards justice, all the aspirations for virtue, and the wellbeing of humanity, shall absolutely vanish.

Wallace eventually opted for a conventional Christian solution, the eternity of spiritual life: ''Beings . . . possessing latent faculties capable of such noble development, are surely destined for a higher and more permanent existence.''

I would venture a different argument. The average species of fossil invertebrate lives 5 to 10 million years, as documented in the fossil record. (The oldest may go back, although I doubt the story myself, more than 200 million years.) Vertebrate species tend to live for shorter times. If we are still here to witness the destruction of our planet some 5 billion years or more hence, then we will have achieved something so unprecedented in the history of life that we should be willing to sing our swan song with joy—*sic transit gloria mundi.* Of course, we might also fly off in those legions of space ships, only to be condensed a bit later into the next big bang. But then, I never have been a keen student of science fiction.

Western Electric
ENGINEERING
RESEARCH CENTER

# We pay these scientists to make our production lines obsolete.

As soon as there's a better way to do something, the old way becomes obsolete.

And these scientists do nothing *but* design new and better ways for Western Electric to manufacture products for the Bell System. In the last two years, they and their colleagues at Western Electric's Engineering Research Center have helped cut costs by over $156 million.

They are a vital part of Western Electric's commitment to helping the Bell System keep the cost of communications service down, while keeping the quality up.

## The Factory's Laboratory

The people at our Engineering Research Center work full time on manufacturing research. Over 50% of them are PhD's.

At home in the factory as well as the lab, they turn theoretical experiments into real savings. For example, while exploring ways to improve production of telephone circuit boards, they invented a totally new material with which to make the boards and a whole new way to mass-produce them.

Another breakthrough is already saving more than $2 million a year. It's a new soldering technique that makes 20,000 connections in less than 60 seconds.

The list of money-saving developments goes on. A new computer program that makes technical drawings in one-fourth the time of manual methods. An automatic system for sorting telephone parts by color. A process that measures the production of optical fiber 1000 times per second, keeping its diameter accurate within 30-millionths of an inch. And there's a new system that takes only 30 seconds to help align tiny integrated circuits that are 200 times thinner than the thinnest human hair.

These are just a few examples of what the Engineering Research Center does throughout *all* of Western Electric's manufacturing operations—developing new ideas in technology to improve telephone products and produce them at lower cost.

## Anticipating the Future

Much of the work of the Engineering Research Center is designed to keep Western Electric ahead of technology, by anticipating what new processes will be needed for tomorrow's products.

It's a total and ongoing commitment. A commitment to provide you with the highest quality telephone service at the lowest possible cost.

*Keeping your communications system the best in the world.*

# Hyenas of the Kalahari

*In the desert, sometimes it pays to be a lone scavenger and other times to feed communally. It all depends on the season*

The night air is filled with sharp, rasping cries and heavy breathing. Dry, brittle grass cracks beneath the stumbling feet of two brown hyenas. Face to face, they spar—now thrusting, now parrying—their long canines glistening white in the moonlight. Then from one comes a high-pitched sound, not unlike a human scream, as its neck is seized by its opponent's powerful, viselike jaws. Dust explodes from the ground as the hyena is shaken like a rag doll and blood spreads through its blond neck hairs. After several minutes, it breaks the adversary's grip and lopes away pursued by the victor. Soon, however, both hyenas return to the carcass they were fighting over and begin feeding side by side as though nothing had happened.

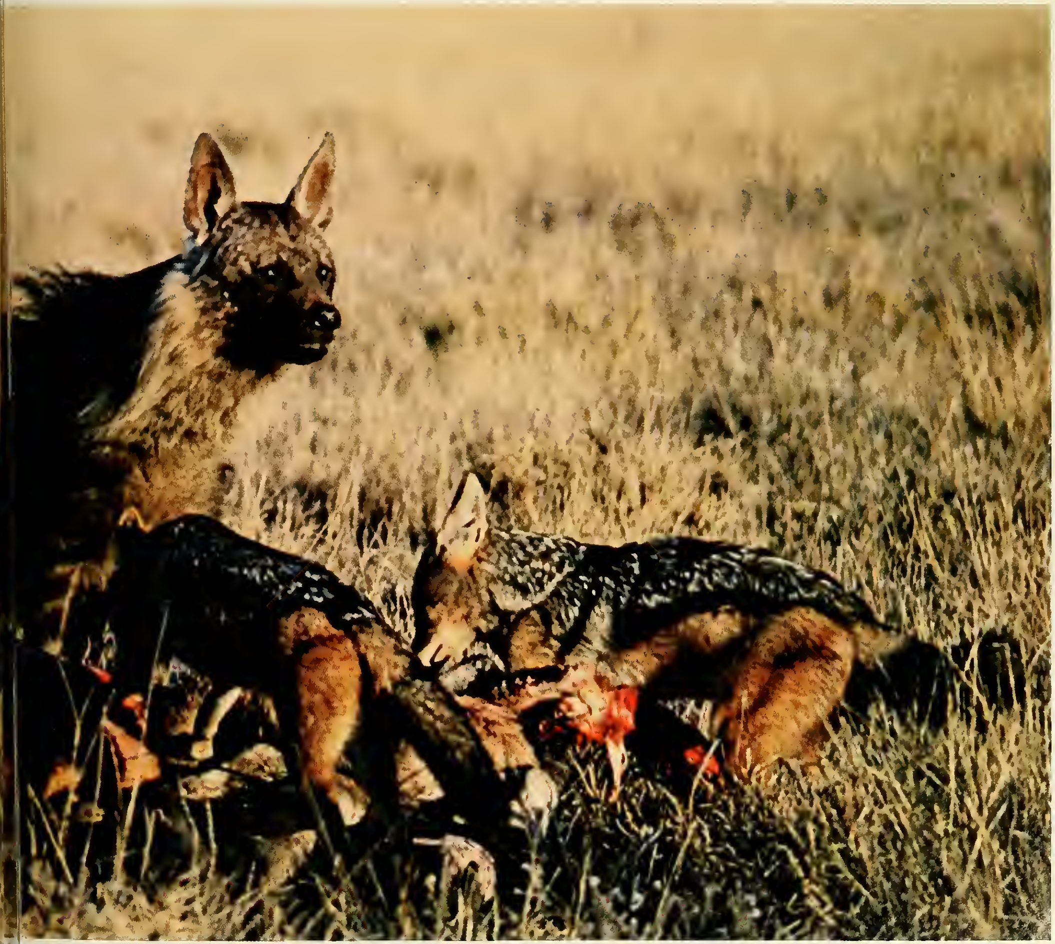
Brown hyenas have always been considered solitary animals, but the above scene involved one of many fascinating social interactions we have observed during a five-year study of these carnivores. Since they are shy and nocturnal, these animals are difficult to study in the wild and have been the object of many misconceptions. In the vast central Kalahari wilderness of

### by Delia Owens and Mark Owens

Botswana, however, we located a population that had probably never before encountered modern man and thus did not fear us.

Confined to the arid and semiarid regions of southern Africa, brown hyenas differ greatly in appearance and behavior from the better known spotted hyena. They have striped gray legs and a long blond mane over the neck, and their sloping back is covered with long dark hair. They stand about two feet at the shoulder and weigh about 110 pounds compared with the spotted hyena's 165 pounds. Of particular interest is the brown hyena's social system, which differs in many ways from that of its spotted cousin.

The brown hyena's social organization is molded by its feeding habits,



*Black-backed jackals swarm over a gemsbok carcass on which a lone brown hyena had been feeding. By disrupting feeding hyenas, the jackals compete effectively as scavengers.*

Delia and Mark Owens

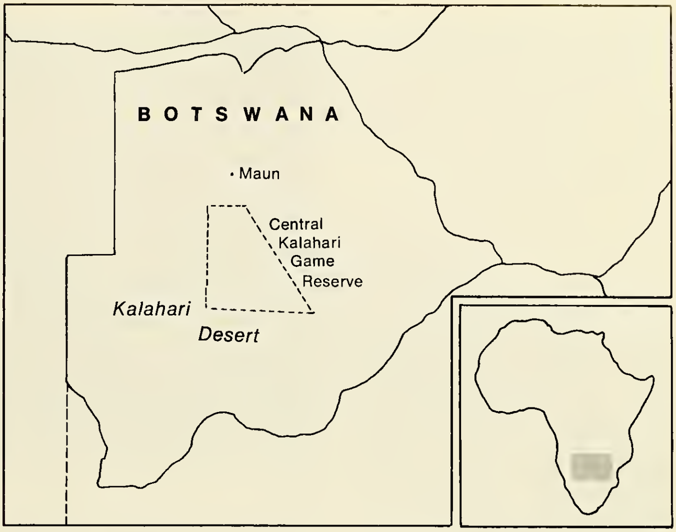
which are dictated by a harsh environment. The influence of niche exploitation on social organization has been demonstrated by Hans Kruuk in his research on other members of the family Hyaenidae. Kruuk has shown that spotted hyenas separate to scavenge or hunt small prey, but they also form highly coordinated groups to hunt larger prey such as wildebeest or zebra. For scattered individuals, each with its own goals, to be suddenly welded into a well-oiled, efficient hunting machine, much social integration must be accomplished in a very short time. Communication by means of complex visual, vocal, and olfactory signals sublimates individual interests and aggression and brings about the cooperation needed for success in the hunt. Thus, spotted hyenas possess a flexible social organization that reflects the size of prey to be hunted.

Another species, the striped hyena, feeds only on small food items—insects, rodents, fruits. Because they do not need any degree of social integration or tolerance to catch small prey, striped hyenas are solitary animals.

The effects of brown hyenas' feeding habits on their social organization can best be understood in terms of the often fickle central Kalahari environment. The seasonality of rainfall, for example, has a strong influence on what brown hyenas eat.

Our research is centered on Deception Valley in the huge Central Kalahari Game Reserve. Seven times larger than the Serengeti Plains, the approximately 33,000-square-mile reserve is one of the largest game protectorates in the world. Except for a few bands of roving Bushmen, we are the only inhabitants of this vast, untouched wilderness. The logistics of working in this remote area, where we even have to make our own maps, are formidable, but the rewards of conducting research in a pristine environment are compensation enough.

The central Kalahari is not a true desert, receiving sufficient moisture—up to twenty inches of rainfall between November and March—to support a cover of vegetation. The area has none of the naked, shifting sand dunes that typify some of the other great deserts of the world. But after the rains the area is dry for eight months or more, and periodic droughts lasting several years are not uncommon.



The topography is gently rolling, homogenous thornveld, transected by three major fossil river systems, the Passarge, Deception, and Okwa valleys. In more pluvial times these ancient river systems carried water to the Makarikari, a huge inland lake to the northeast. Today, these rivers never flow and the valley slopes are stratified with highly diverse habitat types essential to a wide variety of desert species.

The meandering channels of the ancient rivers have become narrow, open savannas where herds of springbok, gemsbok, hartebeest, and a few wildebeest graze on the short, nutritious grasses during the rains. The dune slopes bordering the riverbed are bush savanna, covered with taller grasses and scrub *Acacia*, which sustain such species as eland, steinbok, and duiker. The dune tops sport an open to fairly dense woodland of *Acacia, Terminalia*, and *Combretum* trees, which are browsed by greater kudu and giraffe.

The central Kalahari is also rich in small animals, such as porcupines, springhares, mice, reptiles, and insects, which are seasonally important prey species for all the major predators, including brown hyenas.

Following the influx of prey species to the fossil river valleys at the onset of the rains, lions, cheetahs, leopards, and wild dogs join the resident brown hyenas and black-backed jackals, and the predation frequency increases immensely. With the kills, abundant carrion becomes available to brown hyenas and jackals.

Almost with the last roll of thunder in late March or early April, the sun takes on a baleful look as though determined to burn away every drop of moisture brought by the rains. The long dry season has begun. As the water holes and grasses lose moisture, the springbok, gemsbok, and other plains grazers assume a different life style; they begin including more browse in their diets, leaving the riverbeds for the bushy vegetation found on the dune slopes. The dune soils' deep, porous sand acts as a sponge, soaking up and retaining moisture from the rains. Thus the shrub and herbaceous species growing there remain succulent for long periods, and the browse from these plants sustains the herbivores during the long dry months. By mid-July, the only sign of the past presence of ungulates on the ancient riverbeds are tracks in the crusted mud of dry water holes and dusty game trails that wind along the valley.

Brown hyenas are highly adapted for the role of predator-scavenger in the Kalahari where they must make use of a wide variety of food sources. Their adaptable nature is especially put to the test by the rigors of the long dry season. To avoid the heat, browns are pri-

*Using its rear teeth, a brown hyena gnaws on the rounded stumps of a giraffe's upper leg bones. The huge animal had been killed by lions two nights earlier in the Passarge region of the Kalahari.*

Pe Johnson

*A favored trick of jackals is to sneak up behind a feeding hyena and nip the larger scavenger on its rear. While the hyena whirls around, the swift jackal dashes in to grab a bite out of the carcass. Hyenas will often attempt to chase the jackals, but in hundreds of observed chases, only one jackal was bitten.*

Delia and Mark Owens

marily nocturnal, lying up in holes or under thick bush during the day. After rising in the early evening, a hyena begins a long trek in search of food. Often covering distances of eighteen miles or more in a night, the hyena frequents those habitats most utilized by ungulates and small prey. In this season few items are too old or insipid to serve as food. Months-old bones, horns, and hoofs—the remains of kills made by other predators during the rains—are scavenged and assimilated by the hyena's remarkable digestive system. These remains are present in 33 percent of fecal samples collected at this time of year. Browns also scavenge the dung of large predators and ungulates. A favorite food is ostrich eggs, which are eaten at the nest or cached for a later meal.

Brown hyenas are also predators, and the small prey taken can be an important dietary supplement in the dry season when the carrion resource is much diminished. At this time of year, the hyenas hunt more frequently, spending much less time on the now barren riverbed and more time in the thick bush of the sandveld. The most common prey taken are rodents and birds. Browns also hunt hares, bat-eared foxes, and other small mammals. While insects do not represent a large proportion of the food intake in terms of volume, in the dry months they are found in 16 percent of the feces. Hyenas take an occasional lizard or snake, but reptiles are not important dietary components in the central Kalahari.

Brown hyenas use a simple hunting technique. While they may achieve speeds in excess of forty miles per hour, they are not dexterous in turns. When in pursuit of a rat, the hyena makes a short, lumbering dash; when hunting a springhare, a long zigzag chase. Chases may cover more than a half mile, after which, if successful, the hyena grabs the prey and gives it a quick shake. Browns occasionally stalk birds, lowering their body felid style and taking halting, abbreviated steps before lunging as the prey takes flight. Of all hunting attempts, excluding insects, fewer than 10 percent are successful.

During the dry season, lion prides double the size of their home ranges and are widely scattered. While lion kills are the most important source of carrion, the browns also often appropriate meals from the smaller black-backed jackals. Mammal, bird, and snake kills are stolen from jackals, whose diet consists mostly of small prey they kill themselves. One night as we were following a female brown hyena, she suddenly changed course and ran 450 yards through thick bush to where two jackals had killed a kori bustard. As she dashed in and grabbed the bird, the jackals scattered. Within fifteen minutes, two other browns were attracted to the scene, perhaps demonstrating how important such food items are in the dry season.

Among the most essential elements of the hyena's dry season diet are the fruits of wild melons. Seeds and rinds of the tsama, gemsbok, and hookeri melons make up as much as 50 percent by volume of the animal's dry season feces. There is no standing water anywhere in the central Kalahari for up to eight months, so brown hyenas must extract their moisture requirements from the fluids of prey or from fruits.

Smell is the major sense used in locating food. In many places the hyena cannot see more than a few feet ahead as it walks along in the tall grass and thick bush. Foraging hyenas often turn abruptly into the wind and hold their muzzle high to locate a scent. One adult female we were following turned 120 degrees upwind, raising her muzzle. She then ran a third of mile through thick bush to where a gemsbok was giving birth and attempted to approach it, but moved off after being charged three times.

Of the food items available in the dry season, few are sufficiently large to meet a brown hyena's minimum daily requirement. The hyenas could not profitably forage in groups and must therefore spend much of the dry season traveling alone over large areas.

How does the brown hyena exploit such extremely varied resources as the sparsely distributed food items of the dry season and periodic droughts and the concentrated carrion supplies of the rains? While the brown hyena is an opportunist par excellence, efficient occupancy of the scavenger's niche in such a changeable environment as the Kalahari requires more than simple opportunism. With food supplies ebbing and flowing throughout the ecosystem according to fickle rainfall patterns, how are resources apportioned among individuals during the good and bad times? How does a female find enough to feed herself and her young during the long dry months? Who tends the young while she is foraging, sometimes for days? The answers to these questions lie in the brown hyena's social system.

Like spotted hyenas, browns live in clans. A brown hyena clan consists of three to four adult females, their young of varying ages, a number of suba-

Delia and Mark Owens

dults, one dominant male, and usually no more than two or three subordinate males. The typical clan numbers ten to thirteen animals. Adult clan members maintain a social hierarchy through ritualized fighting that includes neck biting, muzzle wrestling, chasing, and other social displays.

The clan defends a territory of about 100 square miles against neighboring clans. Defense of territory is usually limited to scent marking the boundary; foreign hyenas that trespass are chased and severely bitten on the neck by clan members.

Like many social animals, brown hyenas have a highly developed communication system. Although they do not "laugh" as do spotted hyenas, they possess a repertoire of vocalizations. These are important only for close-range communication, however, and cannot be heard at a distance greater than several hundred yards. The most important means of communication is olfactory investigation of individuals and scent marking. As hyenas traverse their territory, they scent mark, or "paste" anal gland secretions to grass stalks, as often as once every two or three minutes. The paste apparently contains spatial-temporal impressions and information on individual identity and social status, which permit the animals to avoid or locate each other.

One night, for example, Star, a female we have known for five years, pasted a grass stalk at a water hole, then moved south. Twenty minutes later, Patches, a dominant female, approached the pasted stalk, smelled it, and with hackles bristling, altered her course and began walking quickly in the direction Star had taken. She overtook Star about a mile south of the water hole, and chased and neck-bit her for twenty minutes. On another occasion, a hyena threatened another hyena's paste that had become attached to our truck bumper as we drove through the grass. Brown hyenas also paste near such items of interest as carcass sites, water holes, and points where they have cached food.

In their travels, clan members utilize, and maintain through pasting, an extensive network of common pathways, frequently meeting, greeting, and then moving on together or separating to forage alone. When brown hyenas meet, they may simply greet by raising their tails while engaging in mutual anus sniffing, but this greeting often develops into a bizarre ritual we call the "carpal crawl." Lowering itself to its knees with tail raised and lips drawn up in a "grin of appeasement," the subordinate individual crawls around the other. The dominant smells under the tail of the subordinate as both pirouette in a small circle. The dominant breaks contact by simply walking away, only to have the subordinate get up, follow it, and initiate the interaction again by lying down in front of the dominant. We have seen this ritual occur in this leapfrog fashion as many as five times. The entire affair is accompanied by a squeak, sounding somewhat like a rusty gate hinge, emitted by the subordinate hyena.

During the rains, greater amounts of carrion are left on and near the fossil riverbed by the lions, leopards, and cheetahs that focus their hunting efforts on the large ungulates concentrated in the relatively confined area of the range. Carcasses abandoned by lions, or those appropriated by chasing leopards, cheetahs, jackals, and servals from their kills, constitute the most important food resource for brown hyenas at this time of year.

Since brown hyenas depend so heavily on carrion, they have developed distinct relationships with other carni-

vores. They never feed with lions but periodically visit the general area where the big cats are feeding on a kill, taking great care not to venture closer than about 225 yards. The reason for this became obvious to us one night while two large male lions slept within seven feet of the rear of our Land Rover. After some time a brown hyena appeared, moving silently toward us over the bright, moonlit riverbed. The hyena knew us well and approached from the front; the vehicle obscured its view of the sleeping lions. As the hyena passed the rear of the truck, the lions sprang up and began batting the screaming hyena back and forth between them as though playing tennis. Afraid to expose its rear, the hyena kept howling and backpedaling until it finally found an avenue of escape into thick bush at the edge of the riverbed. It was apparently not seriously injured, as we saw it again soon after the incident. Nevertheless, lions do kill browns, and even after a pride has left a carcass for a considerable time, hyenas approach with great caution.

Hyenas frequently chase cheetahs and leopards from their kills. One night a male leopard killed an adult springbok just outside our camp. One of our ear-tagged female hyenas chased the leopard off before it started feeding. Later, the leopard returned to the kill while the hyena was feeding. Raising its tail over its back, the leopard charged the hyena. She countered by raising her tail and mane, then charged straight at the leopard and chased it 500 feet into our camp and up a tree before returning to the carcass. We have also seen hyenas chase leopards into trees on several occasions when there was no kill in contention.

Although spotted hyenas and wild dogs dominate brown hyenas, there are so few of them in the central Kalahari that they cannot be considered serious competitors.

Brown hyenas interact most frequently with black-backed jackals since these little predators are numerous and their diet greatly overlaps that of the hyena. Up to fifteen jackals will compete with a hyena on a carcass, often pulling at one end while the hyena feeds at the other. The hyena frequently interrupts its feeding to chase them off, but the jackals are too quick for the hyenas, and in hundreds of these chases that we observed, only one jackal was bitten across the back

Delia and Mark Owens

*During the rainy season, large herds of springbok, above, and other ungulates provide ample prey for large carnivores. The leftover carcasses are a major food source for hyenas in the Kalahari.*

when it was caught unaware by the hyena. A jackal may at times creep in to nip a hyena on the rear, and as the hyena turns, the crafty little scavenger darts around the opposite side, snatching a piece of the carcass. Jackals are highly effective competitors not only because of the amount they can consume but also because they persistently disturb the feeding hyena.

When a large carcass such as a gemsbok is left by lions, enough meat, skin, and bones remain to attract hyenas for several nights. The hyenas must be able to dissolve individual differences and achieve a state of social tolerance at a carcass so that they can feed together. Behavioral mechanisms such as visual signals, vocalizations, and ritualized contests provide the communication necessary for brown hyenas to associate. Meetings at a carcass constitute a social affair where behaviors such as neck biting, muzzle wrestling, chasing, and the carpal crawl are prevalent.

Neck biting, the ritualized form of combat in brown hyenas, often begins with muzzle wrestling. The hyenas stand face to face, turning their heads this way and that, throwing their muzzles up high and hard against each other. Their mouths are wide open and teeth exposed. Once one of the animals has the other by the neck, the outcome of the contest has been decided. The victor then often shakes the loser so vigorously that the latter's feet are lifted off the ground. The sound of teeth cutting skin can be heard. Finally, the loser is thrown to the ground; the winner stands over it, shaking and biting for up to eighteen minutes. The rattling cry of the now subordinate hyena can be heard for several hundred yards. After disputes of dominance in the social hierarchy are settled by these contests, the hyenas feed together with seldom a sign of aggression.

When the concentrated food resources of the rainy season are gone, the clan's home-range size doubles. Even though they are widely dispersed, clan members maintain contact through the system of olfactory pathways.

The way in which brown hyena females raise their young is ultimately a reflection of their feeding habits. Brown hyena females give birth to one to four cubs in a small maternity den located within the clan's territory. The female attends her cubs once or twice nightly and may move them to three or four new locations. When they are two and a half months old, cubs are installed in a final maternity den near the clan's large communal den. In this location, cubs are gradually introduced to adults and subadults. After a few days in this den, the cubs are carried by their mother to the communal den where they are installed with other young of varying ages. The estrus of adult females appears to be staggered so that only one litter of very young cubs resides in the communal den at any time. The communal den is the answer to the problem of "what to do with the cubs when you have to work all night." It is a type of hyena crèche or kindergarten. Once the cubs are in the communal den, all lactating females indiscriminately suckle cubs until they are approximately fourteen months old. Females, with and without cubs, and young male relatives of the cubs participate in raising the young by bringing food items to the den.

Several advantages accrue to the hyena population from communal denning. After infant cubs are brought to the den, the mother begins spending less time visiting them and is often away for two or three nights. In her absence, the den is the cub's only defense against predators. At the first sound of any animal approaching, small cubs dive through one of the den openings and take refuge in cavities they have previously dug in the walls. Larger cubs "stand tall" at the den entrance. With hackles raised, tails curled over their backs, and heads held high, they present a formidable appearance that often discourages some predators, such as wild dogs, from approaching. If a lion is seen, however, all cubs take instant refuge within the den and stay there until the danger has passed.

Released from the responsibilities of close attendance on cubs, clan females can spend more time foraging. This enhances their chances of locating a carrion surplus, such as a giraffe or gemsbok carcass, portions of which can be transported to the cubs at the den. The advantages of collective food provision by females and the security provided by the den facilitate the survival of all the cubs.

Another benefit of communal denning is that it provides much opportunity for play and social development. Each evening, just after sunset, cubs engage in a riotous "happy hour" of play. Chasing, muzzle wrestling, and neck biting with shaking are all on display as cubs perfect those ritual behavioral mechanisms that will secure them a place in the social hierarchy as adults.

As the cubs reach adolescence, they leave the den for short periods to forage on their own, returning to sleep nearby during the day. At sunset adolescents go to the den to play or rest with smaller cubs until an adult female arrives. After having attended to the cubs, the female leaves to forage, and the adolescent cubs tag along begging food. They also begin learning the network of paths and, in general, the lessons of the scavenging way of life. As adolescents reach subadulthood, however, adults begin rebuffing them with severe neck biting. By about thirty months of age, the young hyenas must forage solitarily, and some males are excluded from the clan.

Soon they will be full adults, with a binary social mode—at times solitary, often social. They will be behaviorally equipped to utilize the seasonal variety of food resources in the central Kalahari ecosystem. During dry times, they will hunt or forage as individuals, and during wet times of plenty, they will come together as social scavengers. Both roles enable them to survive in a harsh land. ☐

Delia and Mark Owens

*Ritualized combat, such as this neck biting at the carcass of a gemsbok, serves to establish relative status within a clan. The biting may be so vigorous that one hyena will be thrown off its feet and its mane colored with blood from open wounds.*

SOME OF THE MOST BEAUTIFUL SCENERY IN NORTH CAROLINA IS INDOORS.

The outdoor beauty of North Carolina is legendary.

Mountains a mile high. Beaches that seem a mile wide. The stuff dream vacations are made of.

But into each vacation, there's a chance that a little rain may fall.

And that's when you'll discover that North Carolina's beauty isn't just on the outside.

Indoors, the sun always shines. From the canvases of painters like Frieseke and Renoir.

You can see the same scenery Monet saw. And flowers created not by nature, but by Picasso.

You can see bones of dinosaurs and great blue whales. Live sea turtles and octopuses. Weathered figureheads from sailing ships.

Things well worth seeing, even when the sun is shining.

You can visit the homes of the famous. Carl Sandburg. Thomas Wolfe. George Vanderbilt. Andrew Johnson.

And the homes of the not-so-famous. In historic cities like Wilmington, Edenton, Beaufort, and the restored Moravian village of Old Salem.

You can watch a pot emerge from a lump of clay. Or a sea bird from a wedge of wood. Or a length of fine cloth from a tangle of rough, raw wool.

And, if you're near a city or college town, the evening's entertainment could range from a world-famous rock star to a Broadway musical.

So, once you see North Carolina outdoors, see North Carolina indoors. If you don't, you could miss some of the most beautiful scenery of all.

*For more information about North Carolina, and a package of free booklets to help you plan your next vacation, write North Carolina Travel, Department 359, Raleigh, North Carolina 27699.*

# Daddy Water Bugs

*The eggs of many species of giant water bugs are carried and cared for by the males*

**Text and photographs by Robert L. Smith**

Giant water bugs of the family Belostomatidae lurk in the shallows of ponds and streams throughout the temperate and tropical regions of the world. These drab brown, flattish insects resemble dead leaves, but their innocuous appearance is deceptive, for all species, from the smallest (two-fifths inch) to the largest (about five inches), are voracious predators. The water bug employs an ambush strategy, waiting motionless for unsuspecting prey to seek sanctuary under its leaflike form. The victim is seized with strong, raptorial front legs and stabbed with a stout, hollow beak. An anesthetic fraction in the water bug's saliva chemically lulls the prey into a terminal sleep. Other constituents of the saliva are proteolytic and immediately begin to liquefy prey tissues. The resultant rich soup is imbibed by the bug through its strawlike mouth.

With few exceptions, giant water bugs are opportunistic, indiscriminate predators. Their rapaciousness is legendary. Although they usually feed on aquatic animals smaller than themselves, they have been reported to attack and successfully subdue prey many times their own size and weight. Several of the larger species regularly capture frogs, water snakes, and fish up to a foot long. There are two independent accounts of large belostomatids having taken plovers. The birds apparently were attacked while wading and managed to struggle ashore with their molesters hanging on tenaciously. A postmortem on one of the plovers found in a moribund condition disclosed that the bug had been feeding on the bird's liver. Their grandest prey is revealed by the common name applied to species that inhabit streams in Mexico and the southwestern United States, "toe biters."

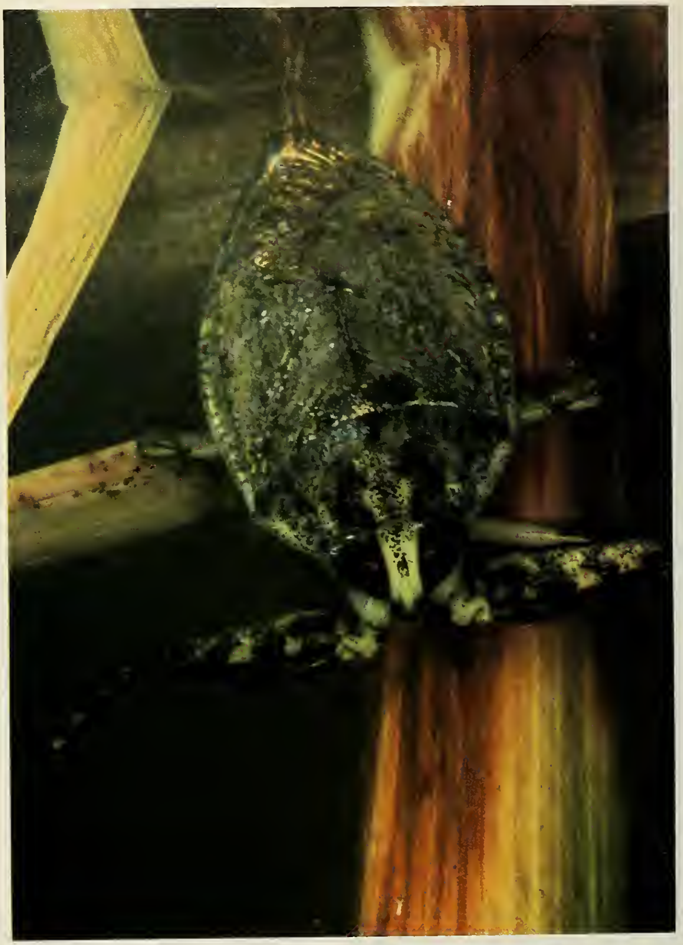
In a vindictive turn of the table, the people of Southeast Asia collect large numbers of giant water bugs, boil them in brine, dry them, and market them as a sort of entomological potato chip. Some cultures in that part of the world value the aromatic thoracic exudate of certain species as a food seasoning.

I was attracted to the giant water bugs, not by their predatory prowess or their ethnoculinary importance, but rather by the unusual reproductive behavior of species belonging to the largest subfamily, the Belostomatinae. Males and females in this subfamily do not follow what we might consider the customary parental roles. Female bugs glue their eggs to the backs of their mates and, having done so, leave the encumbered males to care for and brood the eggs until the young nymphs are hatched, fifteen to thirty days later.

Before the turn of the century, scientists believed that the brooders were females carrying their own eggs. Some (male) authors, apparently influenced by their chauvinistic preconceptions, went to the extent of inventing theories of the oviposition process, which they attributed to a long protrusile ovipositor the female bug was said to extend over her back. It took a woman scientist, Florence W. Slater, to set the record straight, although the charming 1899 report of her discovery reveals something less than complete eman-

*Giant water bugs are voracious predators, often attacking prey many times their own size. Left, a water bug nymph consumes the liquefied tissues of a dragonfly naiad through its strawlike mouth.*

*A water bug (*Lethocerus medius*) waits motionless on a cattail stalk, ready to ambush an unsuspecting victim. "Air straps" projecting from the rear of the bug provide access to atmospheric air.*



*A brooding male (*Abedus herberti*) acquires a store of air at the water's surface. If confined in a tank without foliage for support, such a male will drown unless he is able to kick off his load of eggs.*

cipation. "That the male chafes under the burden is unmistakable," she wrote. "In fact, my suspicions as to the sex of the egg-carrier were first aroused by watching one in an aquarium, which was trying to free itself from its load of eggs, an exhibition of a lack of maternal interest not expected in a female carrying her own eggs." Slater went on to say that when the male was attacked (by an unidentified agent), "he meekly received the blows, seemingly preferring death to the indignity of carrying and caring for the eggs." Not long after, the famous entomologist J.R. de la Torre Bueno, in apparent accord with Slater's humiliated male hypothesis, wrote:

> The egg-bearing male . . . dislikes exceedingly this forced servitude, and does all he can to rid himself of his burden. From time to time he passes his third pair of legs over the eggs, apparently in an endeavor to accomplish his purpose. If he is not able to get rid of it, as sometimes happens, he carries his burden till in due time all the little ones are emerged, when he at last frees himself from it.

These interpretations appear quaint in the light of modern evolutionary theory. Natural selection could not have favored females programmed to dispose of their eggs on the backs of males if these eggs were then to be discarded in places or conditions unfavorable to their development. On the contrary, it is important for oviparous females of all species to deposit their eggs in places that will tend to maximize egg success and give the young the best possible start in life. Following this reasoning, I set out to confirm that the back of a male water bug is the optimal substrate for water bug eggs.

*Belostoma flumineum*, the bug whose behavior previous workers had observed, is one of the most common United States species, occurring in the shore areas of ponds from coast to coast. I quickly located some in a pond at Papago Park in Phoenix. While collecting bugs to establish a laboratory population, I observed egg-covered males perform the remarkable behavior pattern mentioned by de la Torre Bueno: they vigorously stroked the eggs on their backs with their hind legs, which are lined with long swimming hairs. Most applied a series of several strokes with one leg, rested, then stroked repeatedly with the other.

This stroking behavior seemed more nurturant than malevolent. I wondered if the male bugs were performing an essential task, stroking to insure eggs a constant supply of freshly oxygenated water while at the same time removing toxic embryonic metabolites. If so, eggs removed from a male's back and submerged in standing water might fail to develop. In the laboratory, I removed the gelatinous egg pads from the backs of males and placed them in deep dishes. I covered half of these eggs with several centimeters of water; the other dishes were left dry. As a control for this simple experiment, I placed several encumbered males in identical containers filled with water. The next day, I was discomfited to find that a few of the control males had died, and that the rest had somehow removed their egg pads. Slater's and de la Torre Bueno's words flashed through my mind: "dislikes exceed-

ingly," "to rid himself of the burden," "seemingly preferring death."

Turning to the holding tank that contained the rest of the bugs in a tangle of filamentous algae and other aquatic plants, I fully expected males either to have died or to have shed their egg pads, but found most of them resting happily on the aquatic plants with their eggs exposed above the water's surface. Others were below the surface stroking their eggs as I had observed in the field. A small mystery had been solved. Apparently, previous observers had placed egg-laden bugs in aquariums lacking vegetation that would permit passive resting at the surface.

The giant water bug lacks gills. It obtains a store of air at the surface by extending out of the water a pair of special posterior respiratory organs called air straps. The air straps, densely covered with water-shedding hairs, provide a pathway for atmospheric air, which is drawn into a reservoir under the wings, where it is available to the bug through abdominal and thoracic spiracles, or breathing holes. This permits the water bug to be active underwater, much as an aqualung allows a skin diver to explore the depths. But the water bug, like the aquanaut, must surface periodically to renew its supply of oxygen. Female and unencumbered male bugs float effortlessly for prolonged periods with their air straps extended out of the water. An egg-laden male cannot. The mass of the eggs (up to two times the male's eggless weight) weighs him down, altering his center of gravity so that he floats horizontally, with the air straps below the water's surface. An encumbered male must kick his hind legs repeatedly in order to pop his posterior through the surface film and obtain a quick "breath" of air. Apparently a bug cannot long sustain this procedure without exhausting himself and drowning. Little wonder that a male confined to open water should opt to relieve himself of his burden by kicking at the egg pad until it falls off.

As I had anticipated, the unattended eggs failed to hatch. All eggs in static water developed a fungus, and those left in open air desiccated. In contrast, of those left on the backs of males in water containing aquatic plants, 95 to 100 percent hatched. Males had indeed been brooding their eggs by exposing them to atmospheric air and circulating water over them while underwater.

*Abedus herberti*, another species of belostomatid, has evolved a different brooding pattern. It inhabits slow-flowing streams rather than ponds, and apparently sometimes needs all six legs to hold its position against the force of a changing current. Like *B. flumineum*, it frequently rests in emergent vegetation with its eggs exposed to the atmosphere; but when below the surface, rather than stroking, males do "push-ups" (rock back and forth longitudinally) to circulate water over their eggs. Only occasionally do they pat the eggs with a hind leg to confirm their presence. If the egg pad is removed, the male stops brooding.

In observing *A. herberti*, I also found that the brooding male declines to feed on young nymphs, even if very hungry. This inhibition may protect the male's investment if most of the young nymphs he is likely to encounter have recently hatched from his back and hence contain his genes. Significantly, females and unencumbered males are in no way restrained from cannibalizing nymphs. In the contentious ecological economy of these creatures, an unrelated conspecific nymph is a competitor with no value as a mate; its only utility to an adult resides in the calories it contains. Another seemingly peculiar but adaptive form of cannibalistic behavior is the male's habit of "sucking" eggs that fall or are kicked from his back. While these eggs almost certainly contain the brooder's genes, they have little or no chance of developing after being detached from the male. So, the cannibalistic male is simply recovering a portion of his lost investment in the form of nutrient.

Brooding is not without cost to male water bugs. The added weight and irregular wetted surface of the eggs slow a swimming bug considerably, and the dynamics of brooding (push-ups or egg stroking) undermine his cryptic strategy. These factors almost certainly reduce the brooder's predatory efficiency and may subject him to greater risks of predation. Also, a bug cannot spread his wings and fly when they are covered with eggs, so he forfeits dis-

persal options. But by far the most significant sacrifice is the loss of opportunity for polygynous mating: females reject the encumbered male because he has no brooding services to offer.

Females of almost all species have been selected to invest more heavily than males in the production of young. This differential investment begins with the female's production of relatively enormous gametes. Eggs that contain genetic instructions and nutrients are thousands of times larger than sperm, which contain genes and very little else. And where parenting occurs, it is usually the female that is obliged to nurture the embryos and young for a protracted period. Males typically maximize their contribution to the future gene pool by mating with as many females as possible. When a male participates in the rearing of young, he pays a price in time and reduced opportunities for mating. As previously mentioned, nurturant male water bugs forfeit the opportunity to mate for the duration of brooding.

Although exclusive male brooding is exceedingly rare among insects (and other animals as well), reproductive economics have occasionally favored its development. When it does occur, males should be very selfish about whose eggs they brood. A male that contributes to the care of progeny other than his own (or those closely related to him) is said to be cuckolded, and natural selection is extremely intolerant of cuckolds. The genes for such unselfishness would be poorly represented in subsequent generations. A selfish male that broods only eggs or young containing his selfish genes assures their propagation.

Usually, male insects contribute nothing to reproduction beyond sperm and therefore are not threatened by cuckoldry. Paternal brooding giant water bugs are exceptions—they invest heavily and risk being cuckolded!

Female insects have sperm storage organs (spermathecae) that allow them to mate once and lay eggs over an extended period without the need to remate. Stored sperm is a serious threat to male water bugs that receive eggs from nonvirgin females. Males are incapable of determining if a female has previously mated, and because bugs do not pair bond, males do not have the opportunity to jealously guard their mates against alien insemination, as do other animals, including human males. Male water bugs have evolved a different paternity assurance mechanism. They insist on copulating several times with a female before receiving any of her eggs. After the initial round of coupling, a male allows the female only enough time to deposit two or three eggs on his back before he demands to copulate again. In order for a female to deposit all of her eggs on a male's back, she may be required to copulate more than one hundred times, and the alternating bouts of copulation and oviposition may consume up to two days. This is something of a zoological record, but the process serves male interests very well. By observing competitive matings involving a female and two males, one marked by a dorsal stripe (a genetically dominant trait), I have found that brooders are able to assure paternity of virtually all of the eggs they receive from previously mated females. This system protects males against cuckoldry even under fiercely competitive conditions where a single female is repeatedly mated to a series of different males.

A dramatic proof of the importance of this paternity assurance mechanism was provided by another experiment. I surgically removed part of a male water bug's ejaculatory duct, then paired him with a female previously mated to a genetically marked male. Although the surgically altered male coupled with the female, he could not ejaculate into and flush alien stored sperm from her reproductive tract. Consequently, the eggs he received for brooding were fertilized by the marked male. The vasectomized male had been cuckolded.

That males court females is generally true for the animal kingdom. Because of their usually greater contribution to reproduction, the female is selected to be cautious and choosy in courtship. She is careful to mate the best male from among many suitors, assuring that her offspring will have benefit of the best available male genes. Males are generally not so choosy; they tend to be promiscuous because they have little to lose and potentially much to gain from each successful mating. The male demand for willing females almost always exceeds supply, hence females are a "limited resource" for which males must compete vigorously. Competition among males may involve aggression or, more often, elaborate displays. Biologists conclude that females must prefer aggressive, showy mates, because the genes for these male characteristics are so common in animal populations.

What would happen if the male's reproductive investment were larger than that of the female? The water bugs may serve as a model. Although we have no precise measure of how many calories males and females actually invest in reproduction, it is clear that male water bugs make a substantially larger contribution than traditionally expected of their gender. My field studies of *A. herberti* indicate that for at least part of the year (the highly productive summer months) male back space may be limited. Do the females compete for and court their mates?

To some extent, this expectation is fulfilled: it is the female water bug that first and repeatedly approaches an initially passive male, who may reject these amorous advances. But most males answer with display; it is the nature of their display behavior that is unusual.

I was excited to discover that the male courtship display was a modified version of male brooding behavior—push-ups, executed at about ten times the brooding rate. A male's display demonstrates his ability to brood efficiently. Indeed, he shows himself to be so energetic that he can afford to display at a rate several times faster than necessary to assure development of eggs, and the female is duly impressed. It is not that female water bugs understand the relationship between good display and diligent brooding; it is simply that in the long run more eggs from females with a preference for display have hatched. This differential reproductive success has resulted in female populations composed almost entirely of those with the preference.

Although *A. herberti* females prefer mates that display, a heavily gravid female may lay her eggs on the back of a nondisplaying male if he is the only one available. This suggests that even in insects, well known for their fixed patterns of behavior, sexual roles in courtship may depend on conditions of the moment as well as on sex-linked genetic programs. When eligible males are limited, females may take what they can get; when males are abundant, females require a demonstration of their quality.

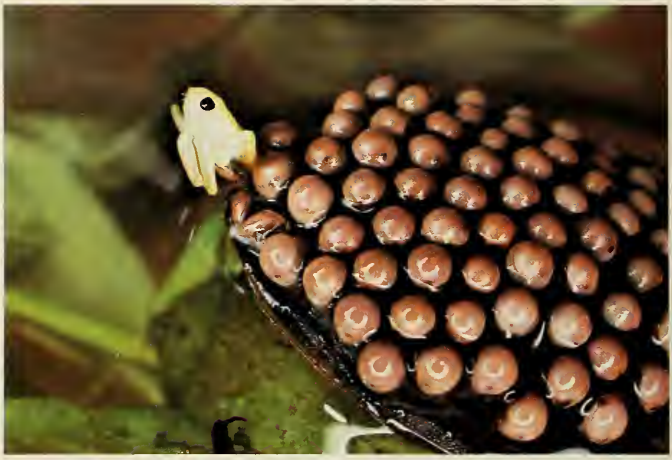
Female water bugs pay a price in time and added risks for male brooding. They could be feeding and making more eggs during the time expended complying with male demands for multiple copulations. Also, females occasionally drop eggs when interrupted by their mates to copulate. Both sexes are almost certainly more vulnerable to predation while mating because of their conspicuousness and preoccupation. But the nurturant father must have his way. He must assure paternity of the eggs he broods or the genes for paternal care will quickly disappear from the population.

Not all male giant water bugs are compelled to brood eggs. Females in what is believed to be the ancestral subfamily, the Lethocerinae, mate and then deposit their eggs on stout emergent vegetation (such as cattails) above the surface of the water. The eggs are left unattended until they hatch, and the young nymphs fall to the water. Male lethocerines are, therefore, at liberty to seduce as many females as possible.

This raises the most intriguing question about water bug biology. How were male Belostomatinae selected to sacrifice unrestrained polygyny for paternal care and serial monogamy? Simply stated: Why did males give up their promiscuous roving ways to become devoted fathers? I think the females had something to do with this.

Primitively, only nonbrooding water bugs must have existed. These species were almost certainly tied to aquatic habitats containing emergent vegetation for oviposition, as are the modern representatives of the group, which are found today the world over. The change in brooding habits must have taken place when, after mating, a "kinky" female, rather than laying her eggs on emergent vegetation, deposited some on a male's back. Actually this event may have occurred repeatedly over a relatively long span of time. Assuming that all brooders evolved from one parent stock, however, their development must have occurred some time before the supercontinent of Pangaea broke up and the continents began drifting apart, for today we find three genera of brooders in the Old World and two in the New World.

Males should have had no particular objection to the aberrant practice so long as they were free to pursue and mate with other females. Presumably, males decorated with a few eggs were no less attractive to conventional females who mated with them and went on attaching their eggs to emergent vegetation. Next we must assume that some eggs hatched from a male's back. When this happened, natural selection had something on which to operate. If the survival of male-borne eggs was greater on average than that of those laid on emergent vegetation, selection would have favored females with a penchant for laying eggs on males' backs. The difference in egg success may have resulted from differential parasitism, predation, and cannibalism of eggs on emergent vegetation over those carried by males. By comparing egg survival in modern brooders and nonbrooders sharing the same habitats, I hope to discover what was advantageous about the new strategy.



*An* Abedus herberti *nymph hatches, above and right. The male promotes the development of his brood by exposing the eggs to atmospheric air, and when underwater, by circulating fresh water over them.*

Whatever the explanation proves to be, male opportunities for polygyny diminished as more females demanded brooding services for their eggs. I suspect that this trend progressed very rapidly to fixation, or genetic universality in the population, such that encumbered males were rejected by all of the females they subsequently encountered. Clearly, males had little choice in the evolution of this new system; they could only attempt to compensate for their diminished opportunities for mating by honing their paternity assurance adaptations and increasing the survival of the eggs they received. Hence the evolution of repeated copulation and the elaboration of male brooding patterns.

Once male brooding had evolved, giant water bugs were no longer tied to habitats containing emergent vegetation. Consequently, the subfamily Belostomatinae rapidly proliferated and its new species invaded almost every possible aquatic habitat, from temporary ponds to the Sonoran Desert streams, where some devoted fathers and liberated mothers first caught my eye and captured my imagination. ☐

# Snakes Shedding Skin

*How limbless ecdysiasts take it all off*

**by Leonard G. Appleby**

Ecdysis, or shedding of the outer epidermis, is one of a snake's most remarkable habits. It so impressed the ancients that they believed the snake to be immortal, being reborn each time it casts its skin. This is understandable to anyone who has seen a snake just after it has sloughed. Its colors then have the appearance of fresh paint and the snake itself is active and alert in striking contrast to its drab appearance and lethargic behavior just prior to skin shedding.

Why does a snake shed its skin? For much the same reason we do (although in scarcely noticeable fashion): to renew the outer epidermis as it becomes worn. Once it has formed, a snake's outer epidermis, or stratum corneum, keratinizes, a process that makes it tougher and more resistant to wear; this is important in view of a snake's close contact with the ground and the considerable friction that results. Keratinization not only makes a snake's integument resistant to abrasion but also prevents excessive loss of moisture from the body. In addition, it forms a barrier to ultraviolet rays, which can be harmful if overabsorbed.

Snakes do not always wait for the stratum corneum to become worn before growing a new one. For an adult snake to follow one sloughing with another within a few weeks is by no means unusual. Just why it does this is not known for certain; with captive snakes, skin shedding in rapid succession usually occurs after a snake has consumed large quantities of food following a period of fasting. As a rule, an adult snake sloughs three to four times a year, at intervals that are sometimes fairly regular, but often vary widely. Skin wounds can cause frequent sheddings, one following close upon another in order to hasten healing. Skin lesions, whether due to injury or disease, show marked improvement—sometimes disappearing completely—when the outer epidermis is renewed. But frequent shedding also occurs in snakes that show no sign of skin injury.

The more rapid a snake's metabolism, the more frequently it will shed; and generally, the higher the temperature, the more rapid its metabolism. There are a number of tropical snakes, however, such as pythons and boas, which are capable of regulating their metabolic rate regardless of temperature. Their metabolism does not necessarily become more rapid as temperature rises because by varying the secretion of certain hormones they can retard their physiological processes and estivate. During estivation shedding is either minimal or nonexistent. Snakes in temperate climates experience temperature-induced high metabolism only during very warm spells. On the other hand, they usually demonstrate a slowed metabolism after a large drop in temperature. When the temperature becomes low enough, they hibernate. Skin shedding does not occur during hibernation, and in the case of a snake that is preparing to slough when it enters hibernation, the process is halted by the prevailing low temperatures and will not recommence until warmer weather returns in the spring.

While its metabolism is dictated by

*An arboreal Central American green viper,* Bothrops lateralis, *begins to slough its outer epidermis. Getting the skin on the head to start peeling is the most difficult part of the process.*

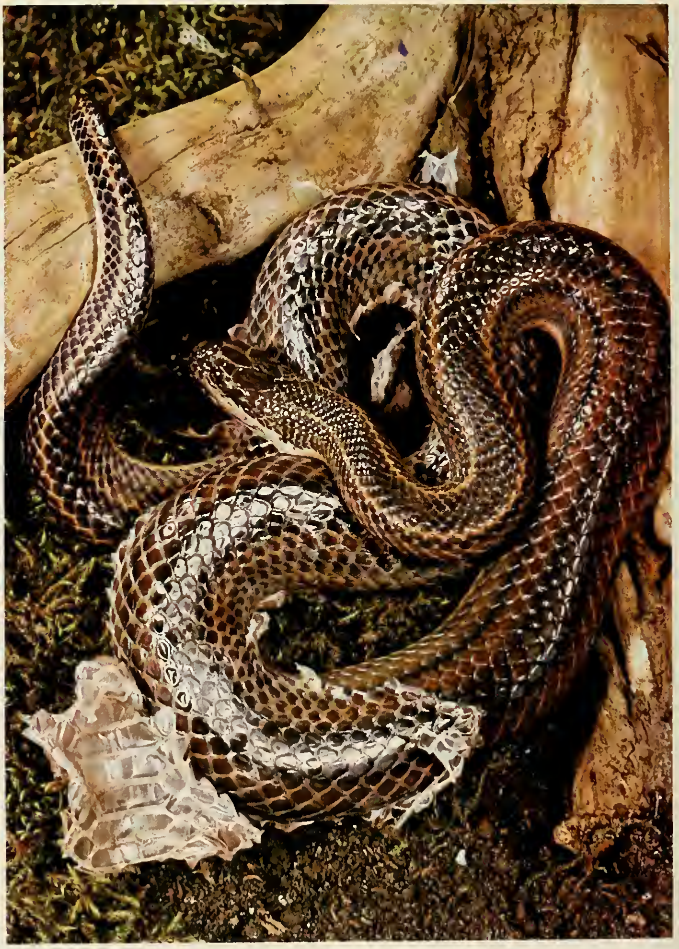
Sherman A. Minton

temperature and hormone secretion, a snake cannot operate at full capacity until there is a substantial intake of food. A snake that begins to feed after a lengthy fast usually eats ravenously. A sudden reawakening of appetite is also likely after shedding, and the rapid intake of a large quantity of food results in such an abrupt acceleration of the snake's metabolism that a second shedding of the skin follows a few weeks later.

Nearly forty years spent studying snakes has brought me to the conclusion that the major influence on the frequency of skin shedding is the amount of food consumed. A snake that feeds greedily sheds its skin more often than does an indifferent feeder. But the subsequent rapid growth in a snake that feeds readily is not the prime cause of frequent sheddings. An aged snake grows very little, if at all, yet it will shed more often when it is feeding well than when disinclined to eat. For example, an aged royal python in my possession, which measured 58 inches when captured, and which has grown scarcely at all in the seven years since then, will shed twice a year if it has fed well over a period of several months. But during fasting, the interval between one shedding and the next has been as long as eighteen months. Like most royal pythons, it is an erratic feeder and frequently fasts for long periods.

In most cases, a sudden disinterest in food signals that a snake is preparing to shed its skin. Gradually, colors dull and markings become less distinct. The ventral scales and the skin between the dorsal scales may take on a milky

*An oily secretion exuded by the underlying skin tissue aids in the removal of the stratum corneum. The old skin of this rainbow water snake is coming off in pieces as it crawls over some tree roots.*

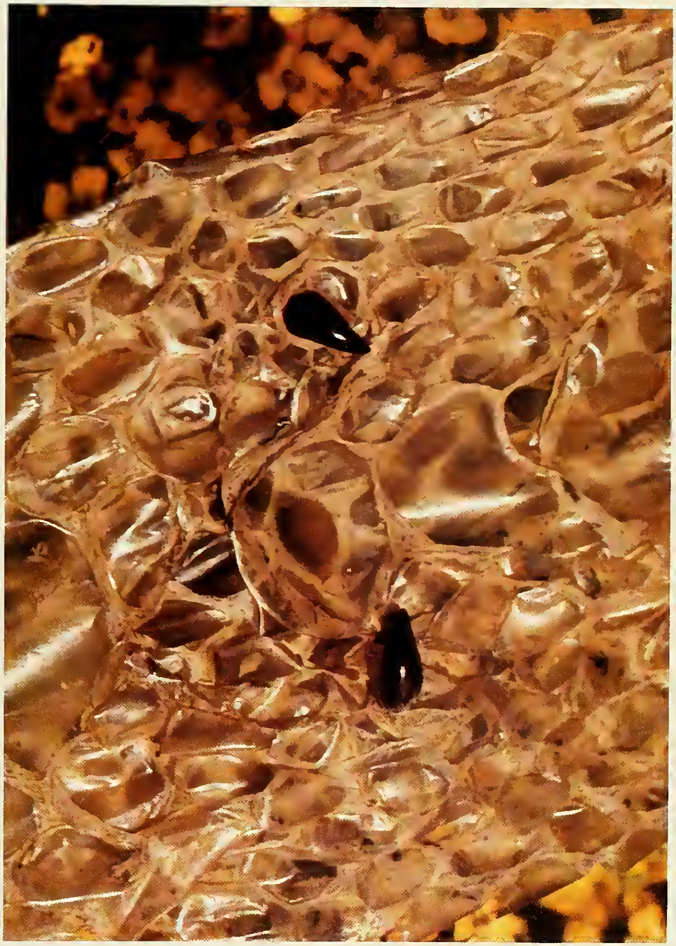


E.R. Degginger

gray color. But not all snake species exhibit this graying phase, and it is often difficult to determine whether they are preparing to shed until the eyes become obscured by a grayish white opacity. All snakes exhibit this symptom, and when its eyes begin to cloud over in this manner, a snake is said to be entering an "opaque." The eye shield's opaqueness is caused by a thickening of the outer layers of skin and occurs as the new stratum corneum starts to form beneath the old one. The thickening epidermis also obscures the colors and markings of the snake, most of which are in the deeper layers of skin. The Brazilian rainbow boa is one snake that does not become drab as ecdysis draws near; instead its beautiful reddish orange color is transformed to a striking silvery white. The length of time the eyes remain obscured varies by species; for most it lasts five to six days, although total opacity is only half that time.

Generally, a snake is largely inactive and prefers to remain hidden since it is particularly vulnerable to attack by other predators while its vision is impaired. A cool climate snake, however, will often emerge to bask in the sun if insufficiently warm in its hiding place. As a rule, a snake that is preparing to shed will not feed, although individuals vary, and some will continue to feed until the eyes become obscured. Others will feed immediately after the eyes have cleared and before the skin has been cast. But most will not feed for several days prior to entering the opaque stage and will only recommence feeding when the old skin has been completely removed.

*Claw casings can be seen on the freshly cast skin of a yellow anaconda. The claws, a feature common to pythons and boas, are located near the vents of the snakes.*



Leonard G. Appleby

*Overleaf: Most snakes become drab as ecdysis draws near, but the Brazilian rainbow boa is not one of them. This snake's reddish orange coloring is replaced by a silvery white at shedding time.*

Leonard G. Appleby

When the moment arrives for the skin to be cast, which occurs between two and five days after the eyes have cleared, the snake awakes from its torpor and becomes restless. To loosen the old skin, it rubs its nose and the sides of its jaws against rough surfaces. Some snakes yawn frequently, an action that sometimes causes the skin to break free from the edges of the mouth. Small snakes will often burrow just below the surface of loose soil and thus start the skin peeling. Normally, shedding begins at the head, and getting the skin to break free at this point often takes the snake longer than ridding itself of the whole skin.

Once it has started to peel, the old stratum corneum usually unfurls rapidly. Separation of the new epidermis from the old is assisted by a secretion exuded by the underlying layers of skin tissue. As the old skin comes away, the presence of this secretion, which also gives some snakes an oily appearance, is revealed by the moistness of the snake's body and the inside surface of the old skin. This sticky secretion causes particles of foreign matter to adhere to the skin that has been cast. Where there is adequate separation between the two layers of skin, removal of the outer one can be completed within ten to twenty minutes.

As the skin comes away from the head, the snake reduces its head rubbing and begins to push its way through dense vegetative growth, where available. The loosened skin catches on twigs and branches, which help to pull it free as the snake moves forward. Any narrow gap through which the snake can squeeze itself will assist in removing unwanted skin, and it is not unusual to find the cast skin of a snake draped in a forked tree branch. While such aids to shedding help to speed the process, they are not necessary. Once the skin is free of the head and forepart of the body, a snake is capable of removing it through muscular action involving alternate contraction and expansion of a small section of the body at a time. This not only loosens the skin, but also pushes it backward toward the tail. The muscular action is, however, only possible up to a point just anterior to the vent. The snake accomplishes removal of the skin covering the tail by moving forward and allowing the drag of the trailing skin to pull it free.

Nearly all snakes can, under favorable circumstances, shed the outer epidermis in one piece. This occurs commonly among the smaller species, but the considerable weight of the large pythons and boas often prevents them from shedding in one piece. Their skin often tears and is shed piecemeal. Many snakes require a certain degree of humidity to be able to achieve a perfect shed. Desert-dwelling snakes, however, and others accustomed to a fairly dry habitat, are able to remove the integument easily and completely no matter how dry their surroundings.

The cast skin possesses none of the colors of its former owner, but may show the markings quite distinctly. Nearly all cast skins are either transparent and colorless or semiopaque and a dirty brown. Depending on the species, some are very fine and delicate; others are coarse and rough. Pythons and boas, which have a pair of claws at the vent position, also cast the outer casing of the claws along with the skin, although these often become detached during shedding and are not always seen on the shed skin. On a perfectly cast skin every scale, including the eye shields, can be seen.

In all cases the cast skin is longer than the snake itself because the connecting skin tissue between the scales, which underlaps them, becomes unfolded and extended during shedding. But the amount by which the cast skin is longer than the snake depends largely on the skin's elasticity, and this in turn depends on the conditions in which it was removed. A skin cast in a very damp atmosphere will stretch considerably more than one that is shed under dry conditions. Consequently, the cast skin of a desert-dwelling snake may be only slightly longer than the snake itself, whereas that cast by a water snake in its natural habitat may be longer than the snake itself by as much as one-fifth the snake's length.

One of the snake's first actions after it has released itself from the unwanted skin is to take a drink of water, if possible. Many snakes not only stop feeding while the new stratum corneum is forming, but also do not drink. There is considerable loss of moisture through evaporation from the body during the actual casting of the skin, and this must be replaced.

Shedding is an important event in the life of a snake, for not only does it acquire a new and roomier integument, but also minor skin wounds are healed and unwelcome parasites such as mites are left behind with the shed skin that lies everted on the ground.☐

*A shedding snake will often squeeze through any available gap so that its loosened skin will snag on protuberances and come free as the snake moves forward. Loose tree bark can serve the purpose.*

# If Wittgenstein Had Been an Eskimo

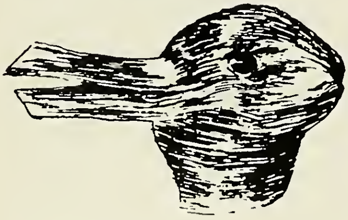
*Even for profound philosophers, literacy has its limitations*

**by Edmund Carpenter**

The philosopher Ludwig Wittgenstein and the art historian Ernst Gombrich contend that we cannot see both rabbit and duck in a single image simultaneously. Illusion, Gombrich says, consists in the conviction that there is only one way of interpreting the visual pattern in front of us. Although we may switch rapidly from rabbit to duck, we cannot experience alternative interpretations at the same time. A shape cannot be seen apart from its interpretation.

Discovering the rabbit in the duck produces, according to Wittgenstein, a surprise not produced by the recognition of either image alone.

Both men, famous for their analytical investigations, chose the same visual pun for intensive analysis and they agreed on its interpretation. Moreover, they invited their readers to play the game themselves and test their conclusions. But how do people from a different background, say Eskimos, perceive visual puns? Can they see the duck and rabbit simultaneously?



Drawing from nineteenth-century German jokebook

Visual punning is an ancient art. A carving from the Canadian Arctic, circa A.D. 1300, simultaneously represents a man in a hooded coat and a dog or, phrased another way, a dog-man, perhaps one popular in Eskimo tales.

I once showed Dali's *Paranoiac Face*, with its double image, to several Eskimos. Painting was alien to them, but visual punning was not; they showed a craftsman's appreciation of skillful work.

Eskimos love visual puns. So do Melanesians and so did the Aztecs. In our own culture, these double images were much favored by surrealists and perhaps have always and everywhere delighted children.

Visual puns vary greatly, but all share one characteristic: each line simultaneously serves two or more images. That is, several figures occupy one space or one figure plays several roles in a single space.

The sheer technical challenge of producing visual puns probably spurs punsters to great efforts. I have seen up to five images in one form. And that form was probably just one aspect of a multisensory pattern in which dance, music, navigation, poetry, and dreams commingled.

Literate man wants none of this. He not only fails to create visual puns but suspects the worst of those who do. Art critic René Crevel, commenting on Dali's puns, says, "It is by a frankly paranoiac process that it is possible to obtain a double image. . . ."

The trouble with this view is that psychotics don't produce double images. Nor do children, although they enjoy them. I say this with confidence because I've searched at length for visual puns in the art work of both and have yet to find one good example. Drawings by psychotics sometimes include what appear, at first, to be puns, but closer examination reveals more confusion than coherence. By contrast, Eskimo punsters demonstrate superb control of multiple perspective. "Art, being bartender," wrote Randall Jarrell, "is never drunk."

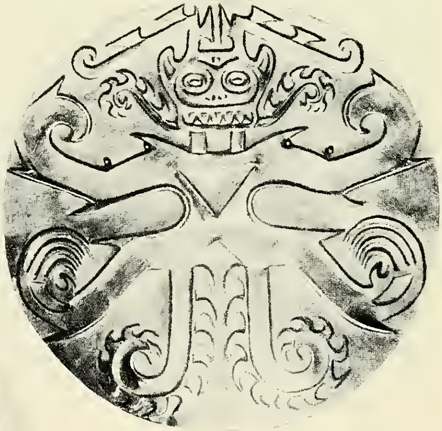
And puns, being art, are rarely accidental. Of course, the punster may deny his work. A Madison Avenue designer who produced an erotic pun called it an accident. So did the designer of a 1951 West German stamp commemorating Hans Böckler: inverted, Böckler became Stalin.

But visual puns don't just happen. They aren't the scribblings of children or madmen. They don't belong in philosophical seminars or psychology labs. And they are not gimmicks designed to surprise. They are deliberate works of art.

For years I regularly asked students to draw visual puns and keep diaries of their efforts. With rare exceptions, each student started with one image, then tried to superimpose a second image. The results, as art, were awful, and the diaries were records of frustration.

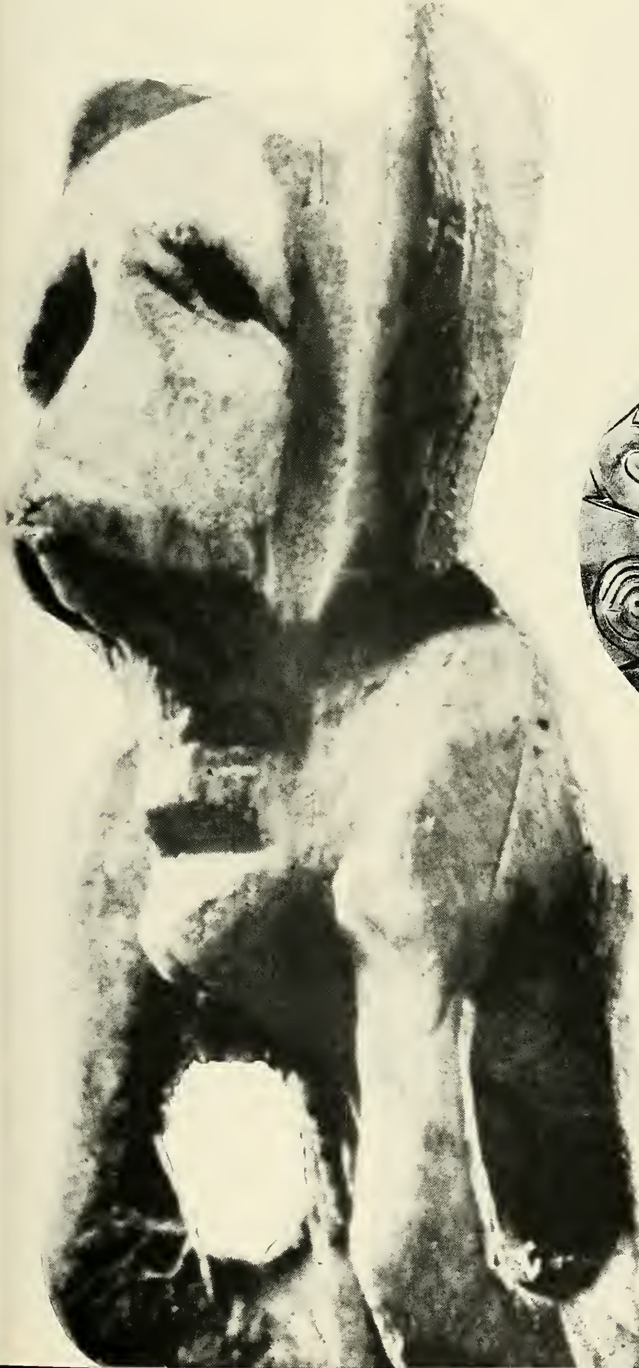
In contrast, an Eskimo carver, having "discovered" a pun in unworked ivory, releases it: the image steps forth in all its complexity. Or a pun may appear to a dreamer, who then executes its likeness.

Such puns are implosive, like the dreams or myths from which they come. An Eskimo myth may include both cause and effect, the way a missile's fuel is its engine and its engine is its fuel. Entire Eskimo societies are



*When inverted, a pre-Columbian gold plaque from Coclé, Panama, reveals a second head with a crown.*

University Museum, University of Pennsylvania



*A dog and a man can be visualized in this carved Late Dorset Eskimo figure, circa A.D. 1300, from Mill Island, south of Bassinland.*

National Museum of Canada

implosive: everybody is simultaneously involved with everybody. There is no isolated self and no elevation of sight over the other senses.

This emphasis on sight is literate man's mark and strength, but the other senses suffer correspondingly. If used at all, they are used like sight. All experience is translated into visual models. We say, "Let's see what we can hear."

The increasing number of native authors—voices from the inside—is one of the most interesting features of contemporary anthropology. These intruders into the visually oriented profession of anthropology are always writing about how things smell, taste, feel, sound: toes gripping roots along a slippery bank; peppery food burning the rectum; "he became aware of gentle heat playing on his right cheek, and a fine smoke teasing his nostrils; while on the left he heard an odd gurgling sound. . . ."

These inside reports, with their descriptions of sensory awareness and involvement, reveal how misleading the traditional, outside "observations" have been. My impression of much tribal art is that it should be embraced, all senses involved, not simply viewed. Putting it on display is like displaying an old, cuddly doll behind glass.

Not long ago, when some British children were asked, "What are the twelve loveliest things you know?" one boy answered:

The cold of ice cream.
The scrunch of dry leaves.
The feel of clean cloze.
Water running into a bath.
Cool wind on a hot day.
Climbing up a hill, looking down.
Hot-water bottle in bed.
Honey in you mouth.
Smell in a drug store.
Babies smiling.
The feeling inside when you sing.
Baby kittens.

A girl's list went like this:

Our dog's eyes.
Street lights on the river.
Wet stones.
The smell of rain.
An organ playing.
Red roofs in trees.
Smoke rising.
Rain on your cheeks.
The smell of cut grass.
Red velvet.
The smell of picnic teas.
The moon in clouds.

About 1900, Enos Mills, a mountain guide, became snow-blind in the Rockies at 12,000 feet. "My faculties," he reports, "were intensely awake." He could not use trails because of the depth of snow. Carrying a long staff, he set out on snowshoes to find the blaze marks on trees, which he had made on his forward journey. Making his way from tree to tree, he thrust an arm into the snow, feeling the bark of the trees until he discovered the marks of the blaze. He resorted to the trees for the points of the compass. He knew that the canyon walls facing south carried pines, while those facing north carried spruce. Keeping pines on his left, he traveled to the eastern side of the range. To check this, he examined lichens on low-lying boulders and moss encircling tree trunks, concluding that the area admitted light freely from all quarters. He shouted, noted from which direction the echoes came, their intensity and cross-replies, and concluded that he was going into the head of a deep forest-walled canyon. In the night a snowslide almost smothered him; enormous rocks and entangled branches made his progress more difficult. Suddenly he caught the scent of aspen smoke. Under favorable conditions a person with a keen sense of smell can detect burning aspen for several miles. Going forward into the wind, he emerged from the woods where the smoke was strongest and knew a cabin was near. In fear of passing it, he stopped to use his ears. As he stood listening, a little girl gently, curiously asked: "Are you going to stay here tonight?"

Children learn to separate their senses when they learn, in class, to read silently. Their legs twist, they bite their tongues, but with enormous effort they learn to fragment their senses, to turn on one at a time and keep the others in neutral. And so they are indoctrinated into that world where readers seek silent solitude, concert-goers close their eyes, and gallery guards warn, "Do not touch."

All this is alien to Eskimo experience. Once, with visibility zero, I traveled rapidly along a dangerous coastline, guided by an Eskimo who navigated by the feel of wind and smell of fog, by sounds of surf and nesting birds, and particularly by the feel of the pattern of waves and current against his buttocks.

With such interplay and interpenetration of senses, no single sense can be isolated. An Eskimo hunter who relied on sight alone would return empty-handed; a traveler who ignored odors and winds and sounds would soon be lost.

Recently, comparing paintings by blind children with those of seeing children, an experimenter found the two indistinguishable until the age of about six, at which point the seeing children moved in the direction of optical imagery.

Patients who have undergone throat surgery are forbidden to read, for there is a natural tendency for a reader to evoke absent sounds, and the throat muscles work silently as the reader scans the page.

Nothing was more alien to medievalism than silent reading. Reading was aloud, often as song, with gestures. Physicians prescribed reading as

Paranoiac Face, *by Salvador Dali, 1934/35*

*The surrealistic landscape of Max Ernst's* Totem and Taboo, *painted in 1941/42, contains bizarre faces, giant birds, and other hidden images.*

a form of exercise. Isolating one sense from all others calls for enormous training and self-control; it is probably never fully achieved. Test this yourself. Run water into the bath while switching the light on and off: the sound seems louder in the dark.

Phonetic writing translated multisensuous speech into one sense only. The peculiar effect of translating the many senses of the spoken word into the visual mode of writing was to abstract one sense from the cluster of the human senses.

The phonetic alphabet and all its derivatives stressed a one-thing-at-a-time analytic awareness in perception. This intensity of analysis was achieved at the price of forcing all else in the field of perception into the subliminal.

Literacy ushered man into the world of the divided senses. The value accorded the eye at the expense of all other senses destroyed the harmonic orchestration of the senses and led to emphasis upon the individual experience of the individual sense. It created a hierarchy of senses with sight highest, touch lowest. Aristotle, in the first sentence of *Metaphysics*, says, of all the senses, trust only the sense of sight. Plato went further: he regarded sight as the highest and touch as the lowest.

Sight is like no other sense: it favors detachment. I am *in* sound and smell; taste is *within* me; and touch presses *against* me. But with my eyes I become a detached observer, casting a hard eye on all experience.

Literate man takes literacy for granted, as if this sensory imbalance were a natural state. Yet the silent, immobile reader needs as much food as a miner, more sleep than a farmer, and clothing to conserve his energies. You cannot teach a naked man to read.

Literate man, observing a pun, first recognizes only the image rendered vertically relative to himself. The art historian Siegfried Giedion tells of a paleolithic carving of a horse that was on public display for decades. When the heavy stone was rolled outside to be photographed, everyone saw, for the first time, a second horse, inverted.

In both paleolithic and Eskimo art, images are not rendered in relation to the viewer. When handed a photograph, Eskimos examine it as it is handed to them, no matter how it is oriented. They look at maps from any direction, and if they understood English, I'm sure they would enjoy James Thurber's NOW NO SWIMS ON MON without turning it.

One may describe the alteration from duck to rabbit as a perception, as if the object had altered before one's eyes. But the picture doesn't change, just the observer's impression of it, point of view, emphasis upon one or-

ganization over another. Suppose, however, the observer has no "point of view" or, more accurately, none resembling the private, delimiting one of literate man. Suppose the observer's art, language, and entire culture deny privacy and stress, instead, group awareness. Suppose, finally, no effort is made to suppress the "baser" senses or to make sight supreme.

Suppose all this and you have gone a long way toward describing Eskimos, who have no private point of view because they don't "view" life or conceive of an individual as a "point."

The artist M.C. Escher, whose visual puns have fascinated mathematicians, wrote:

> The border line between two adjacent shapes having a double function, the act of tracing such a line is a complicated business. On either side of it, simultaneously, a recognizability takes shape. But the human mind and eye cannot be busy with two things at the same moment and so there must be a quick and continuous jumping from one side to the other.

Does the Eskimo, like Escher, switch from one reading to another? Or can an Eskimo hold two disjunctive alternate readings simultaneously? We know that a literate person can recite a poem and meanwhile solve simple arithmetical problems. But while one is attended to, the other goes below some kind of threshold.

Other cultures seem to differ in the way they handle this kind of multiplicity of thought. Certain African groups can carry on five simultaneous rhythms: the melody and four percussion parts. All players often have their own downbeat. Three rhythms are common in preliterate music: melody, hand clapping, and foot tapping. This is extremely difficult for literates who "automatically" keep step to the music.

And the Eskimos, do they *actually* see the duck and rabbit simultaneously? Perhaps not, but they certainly see them faster, and in quite a different way, than Ludwig Wittgenstein. ☐

# Quasars Confirmed

*After more than a decade of controversy, the cosmological theory of these objects has been substantiated, establishing that quasars are the most distant and powerful sources of energy in the known universe*

According to the cosmological theory, the large red shifts found in the spectra of quasars are due to the expansion of the universe. In our universe, all the galaxies in space are rushing away from each other. The more distant a galaxy, the faster it is receding and hence the larger its observed red shift, which is caused by the Doppler effect. Since most observed quasars have larger red shifts than most known galaxies, the cosmological theory implies that the quasars are farther away than the galaxies.

Other theories have variously ascribed the red shifts of quasars to powerful gravitational force within each quasar; to a postulated violent expulsion of quasars from an explosion within our own Milky Way (or a neighboring galaxy); and to various new, unproved, and speculative physical effects. In all cases, these alternative theories state that quasars are less distant than indicated by the cosmological theory.

"Quasar" is an invented word, short for "quasi-stellar radio source." It stands for a celestial source of radio waves that resembles a star when seen through a visible-light telescope but that is *not* a star.

Most astronomers have accepted the cosmological theory of quasars ever since it was proposed in 1963. Like any other "established" theory, it has had a small number of vocal critics. In this case, however, the critics have included several of the world's most accomplished and distinguished astrophysicists.

The basic objection to the cosmological theory was raised because it implies that quasars are extremely powerful energy sources. If quasars are as far away as the theory tells us, then we can deduce that the radio emission of a typical bright quasar may be 1,000 times greater than the total of all forms of energy radiated by the hundreds of billions of stars and many nebulae of the Milky Way galaxy. Yet, such a quasar is about 30,000 times smaller than our galaxy. Further, some quasars emit even more energy in the form of infrared waves, visible light, and X-rays than they do as radio waves. To critics of the cosmological theory, it seemed unreasonable to suppose that so much power can be generated in so small an object.

To avoid this energy-production dilemma, some researchers decided that quasars must be much closer than indicated by the cosmological theory. If they are closer, then it follows that a quasar produces much less energy than estimated above. Also, the red shifts of quasars must then be produced by something other than the expansion of the universe.

Many astrophysicists believe that a quasar is a type of immense outburst in the center of a galaxy referred to as the "underlying galaxy." In that case, the light of the quasar would far exceed that of the underlying galaxy and it would be very hard to photograph the galaxy. Thus, the claimed existence of underlying galaxies would not contradict the fact that quasars generally look like isolated spots of light on telescopic photographs.

To check the cosmological theory, astronomers have searched for evidence of an association between galaxies and quasars. The two principal techniques have been to look for the underlying galaxies and to look for galaxies that occur near quasars.

Galaxies occur in two kinds of concentrations, strong ones called clusters and more diffuse ones called groups. All of the galaxies in a remote cluster or group are at roughly the same distance from the earth and thus have roughly the same red shifts. Clusters are such pronounced concentrations that they can be easily recognized on the *Palomar Observatory Sky Survey* (a standard atlas of deep space). Hence, many of the clusters that appear in the *Survey* have been cataloged and studied. They don't seem to contain quasars. But the weaker concentrations, or groups of galaxies, are hard to spot on the *Sky Survey* and most of them have not been cataloged. If quasars were found to occur in galaxy groups, and to have red shifts equal to those of the member galaxies, it would be clear that the quasar and galaxy red shifts are caused by the same process. Since galaxy red shifts are due to the expansion of the universe, such a discovery would prove the cosmological theory of quasars. Likewise, the detection of an underlying galaxy with the same red shift as its quasar would be strong evidence for this theory.

According to a 1973 report by a Hale Observatories astronomer, Jerome Kristian, underlying galaxies would most readily be detected as dim "fuzz" around the photographic images of the nearest quasars. Such fuzz has in fact been observed around several of the nearer quasars. This has been interpreted as evidence for the proposal that quasars are explosions in galaxies. Nevertheless, it did not confirm the cosmological theory, since it has not usually been possible to measure the red shift of the dim fuzz in the presence of the overwhelming light of the quasar. And even when fuzz is found around a quasar, that fuzz may not be an underlying galaxy but something else, for example, gas clouds ejected from the quasar.

Going one step further, if the fuzz is photographed well enough to show that it really is a galaxy, and if the red shifts of the fuzz and the quasar are measured and found to be equal, there may still be a loophole. Critics of the cosmological theory can claim, in such by Stephen P. Maran

a case, that what was photographed is just an unusual galaxy with a very bright nucleus and not a quasar at all. Thus, I have always felt that the hunt for underlying galaxies would not provide the most clear-cut proof of the cosmological theory.

Over the past decade, there have been several reports of red shift measurements for adjacent quasars and galaxies. In some cases, the quasar-galaxy pair were found to have nearly the same red shifts and those cases were claimed as evidence for the cosmological theory. In other cases, the adjacent galaxies and quasars were found to have widely different red shifts. This was taken to mean that quasar red shifts do not result from the same process as galaxy red shifts. Yet, for either conclusion to be drawn, the quasar and galaxy must actually be the same distance from the earth. The possibility always exists that, as seen from the earth, one object is in the foreground and the other far behind, so that they only seem to be next to each other. To resolve the issue, a careful survey of a statistically meaningful number of quasars was needed.

In July 1978, I was surprised to learn that a galaxy near the quasar 3C273 had been found to have the same red shift as the quasar. Although this might be just one more report of an isolated quasar-galaxy pair, an individual case with little statistical significance, I found the discovery remarkable because 3C273 is the brightest and best known of all quasars. It is actually visible in amateur astronomers' telescopes and its picture appears in nearly every modern textbook on astronomy. I had not imagined that the astronomers working on tests of the cosmological theory could have overlooked a galaxy near 3C273. For fifteen years, the largest telescopes in the world had been used to investigate quasars and espe-

cially the problem of their red shifts. But hindsight shows that many of the studies had a scatter-gun character or were even directed up blind alleys. The 3C273 finding, in contrast, was made by a young astronomer with a medium-sized telescope, as a byproduct of the first truly systematic investigation of the red shifts of galaxies near quasars.

The young astronomer was Alan Stockton of the Institute of Astronomy in Honolulu. Stockton had trained in quasar research at the University of Arizona in the late 1960s and has specialized in such studies ever since. His systematic investigation of galaxy red shifts appeared in the *Astrophysical Journal* in August 1978.

Stockton assumed that quasars *do* occur in groups of galaxies and that the cosmological theory of quasars is correct. He reasoned that a careful search of an area around each quasar, chosen so that the area is no greater than the size of a typical galaxy group, should reveal faint galaxies with the same red shifts as the quasars. The important thing was to use a fair number of quasars, chosen by a statistically valid means, and thereby avoid the criticism of the much-disputed, isolated cases reported by earlier researchers. Stockton selected twenty-seven quasars, all of them close enough to the earth (according to the cosmological theory interpretation of its red shift) so that galaxies in their vicinities would be visible on the *Palomar Observatory Sky Survey.* The quasars also had to be positioned in the sky so that they were observable with his telescope in Hawaii.

For each of the quasars, Stockton searched a circular area on the *Sky Survey*, with a radius of 45 arc seconds—about equal to the diameter of the planet Jupiter as seen from the earth. He also made new photographs, to insure that small, dim galaxies were not mistaken for stars or vice versa during the *Survey* inspection. Seventeen of the quasar areas were found to contain a total of twenty-nine galaxies, while ten were "empty." Some quasar areas contained up to three galaxies.

Stockton photographed the spectra of the galaxies with an 88-inch telescope atop Mauna Kea, on the island of Hawaii. He identified lines in the spectra of twenty-five of the twenty-nine galaxies and measured their red shifts. Of the twenty-five, thirteen (more than half) have red shifts corresponding to velocities of recession that are almost equal to those of the nearby

quasars. These thirteen galaxies are located in the areas surrounding eight of the quasars. All the other twelve galaxies differ in recession velocity from their "nearby" quasars, with a wide range of velocity difference: ten of the twelve have recession velocities that are over 15,000 kilometers per second (9,300 miles per second) smaller than those of the quasars, computed according to the cosmological theory. These much smaller velocities (red shifts) imply that the twelve galaxies are foreground objects.

If there were no relation between the quasars and the galaxies, there would be little or no clustering among the velocity differences that Stockton measured. But, as mentioned above, about half of the galaxies have nearly the same recession velocity, or red shift, as their adjacent quasars. (They agree to within 1,000 kilometers per second.) The odds are vanishingly small that this result is a statistical accident. In fact, Stockton calculates the odds at less than one chance in 1.5 million. The only reasonable interpretation of his red shift measurements is that a fair number of quasars occur in groups of galaxies and that they have the same red shifts as the member galaxies of the groups.

Stockton's investigation seems to prove the cosmological theory of quasars. His report appeared more than a year ago but no significant objection to it has so far been made. Yet, what he did was well within the capabilities of the major astronomical observatories of the world more than a decade ago. Last November I asked a leading authority on quasars why no one had carried out this project earlier. The answer, I was told, is that no one had worked hard enough at the problem. Many cleverly planned single observations had been made by others, but only Stockton had been willing to invest the time to make systematic spectroscopic observations of many very dim galaxies.

The confirmation of the cosmological theory of quasars was thus simply the happy outcome of long hours at the telescope. Twenty-five red shifts turned out to be more informative than any number of profound and imaginative astrophysical speculations.

# Sunken Treasure

Living Corals, by Douglas Faulkner and Richard Chesher. *Clarkson N. Potter, Inc., $45.00; 310 pp., illus.*

Tropical coral reefs inspire a fascination that has generated a large volume of publications, both scientific and popular. No single work could begin to adequately describe these massive and complex structures, and information tends to be scattered throughout a multitude of books and periodicals. Collecting these materials for study is routine for the worker in marine biology but beyond the resources of the general public. Guides and manuals have been compiled for identification of reef organisms; in the case of corals, these publications deal primarily with dead skeletons, and pictures and descriptions of the living forms are infrequent and scattered. The appearance of *Living Corals* would seem an important step toward filling a gap in the literature, although this does not seem to be the intent of the authors.

Diver-photographer Douglas Faulkner has presented a collection of 194 spectacular color photographs of reef corals. Seldom has the beauty of these organisms been so dramatically illustrated. Selection of the photographs to be included, as well as the conception of the text, was apparently based primarily on aesthetic considerations, which is at once both the strength and the weakness of the book. What results is a hard-cover slide show, intended to entertain and inspire rather than inform.

Certainly *Living Corals* has all the makings of a weighty tome: larger-than-life photographs of 117 species of living corals, covering 31 families of both hard and soft varieties; taxonomic verification by leading experts in the field; collection data and reference specimens deposited in the collections of the Smithsonian Institution. The book's review of the natural history of the reef is highly personal but generally informative and well written.

For these efforts the academically oriented reader can be thankful. As with extracting the pearl from the oyster, however, there is a lot of other material to get through in the process that may not be to one's taste. In his commentary, Faulkner argues that his photographs should stand alone as testimony to the wonder of the reef, with no running commentary to detract from visual delight, but the realities of the publishing world apparently forced a compromise of this ideal. The resultant union of art and science is a somewhat awkward marriage of convenience. Isolated in pristine magnificence, the photographs occupy the body of the book. Explanatory notes for each of the illustrations are grouped together in a separate section at the back. Reference to these "captions" is made by numbers positioned discreetly beside the photographs. This arrangement results in an annoying need for flipping pages back and forth between sections, a process made more difficult by the absence of an index and a not-too-robust binding that failed after the first day of this kind of treatment.

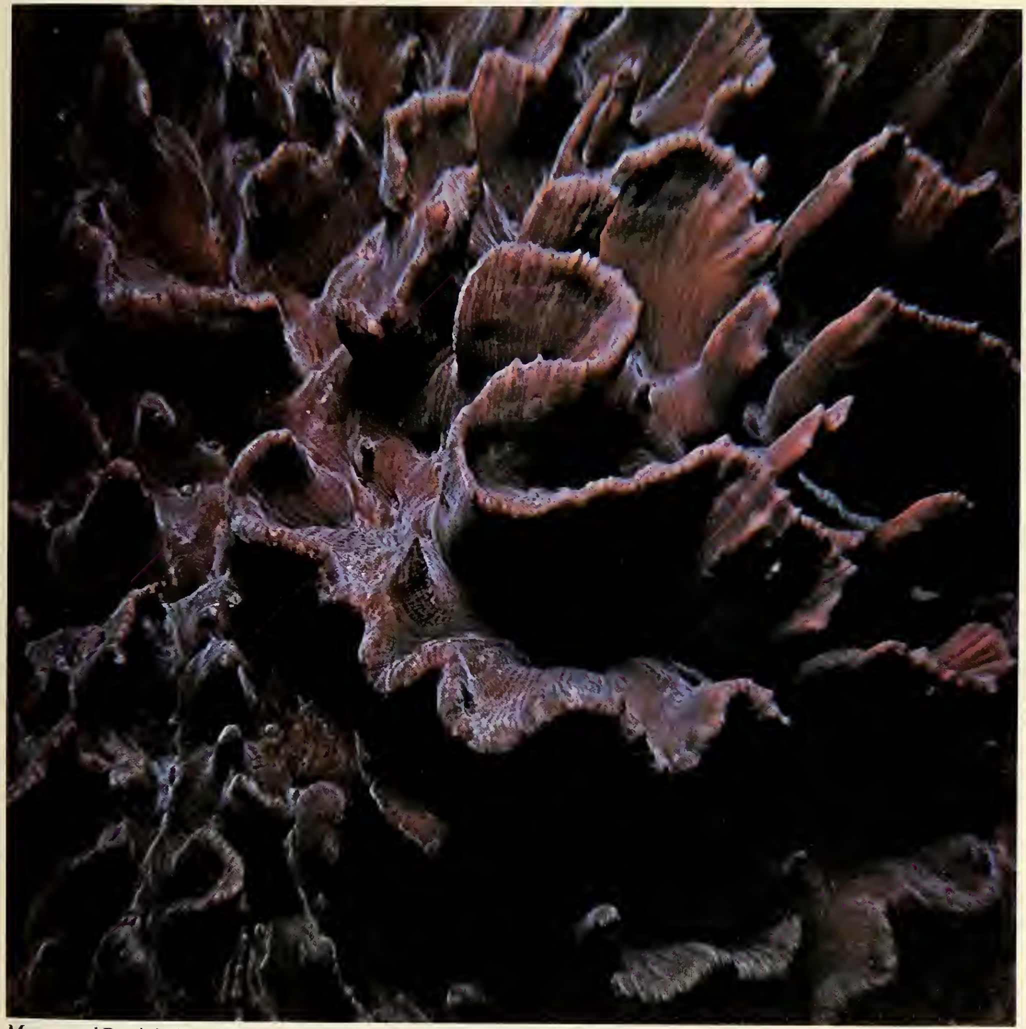
The scientific presence is further diluted in the notes, where information is offered in a haphazard fashion. The inquiring reader, seeking enlightenment about a particular life form discovered in a photograph, frequently finds little more than highly personal reminiscence or sentimental imagery, occasionally spiced up by a whimsical selection of common names invented by the author, such as, "She Loves Me Not Daisy Coral" and "Purple Polyped Plankton Eater Coral."

The rate of discovery in reef research usually outstrips the rate of publication, and much information is outdated before getting into print. Many of the concepts presented in this book have suffered this fate, especially in relation to reef geology and sea level. Although the Pacific's apparent sea level has generally fallen for the last 5,000 years, this is not true everywhere; impossible as it may seem, the opposite has occurred in the Indian Ocean and the Caribbean. Measurements of sea level change are not equal in all parts of the globe. The surface of the world ocean is perceived only in relation to its impingement upon land, even though it may be at a uniform position. The upward or downward movement of land masses affects the apparent rise or fall of sea level on a local scale.

A certain romanticism colors much of the presentation of reef ecology. The concept of the coral reef as a "superorganism" can create as many problems as it explains, erroneously setting the reef apart from other similarly complex and ancient ecosystems.

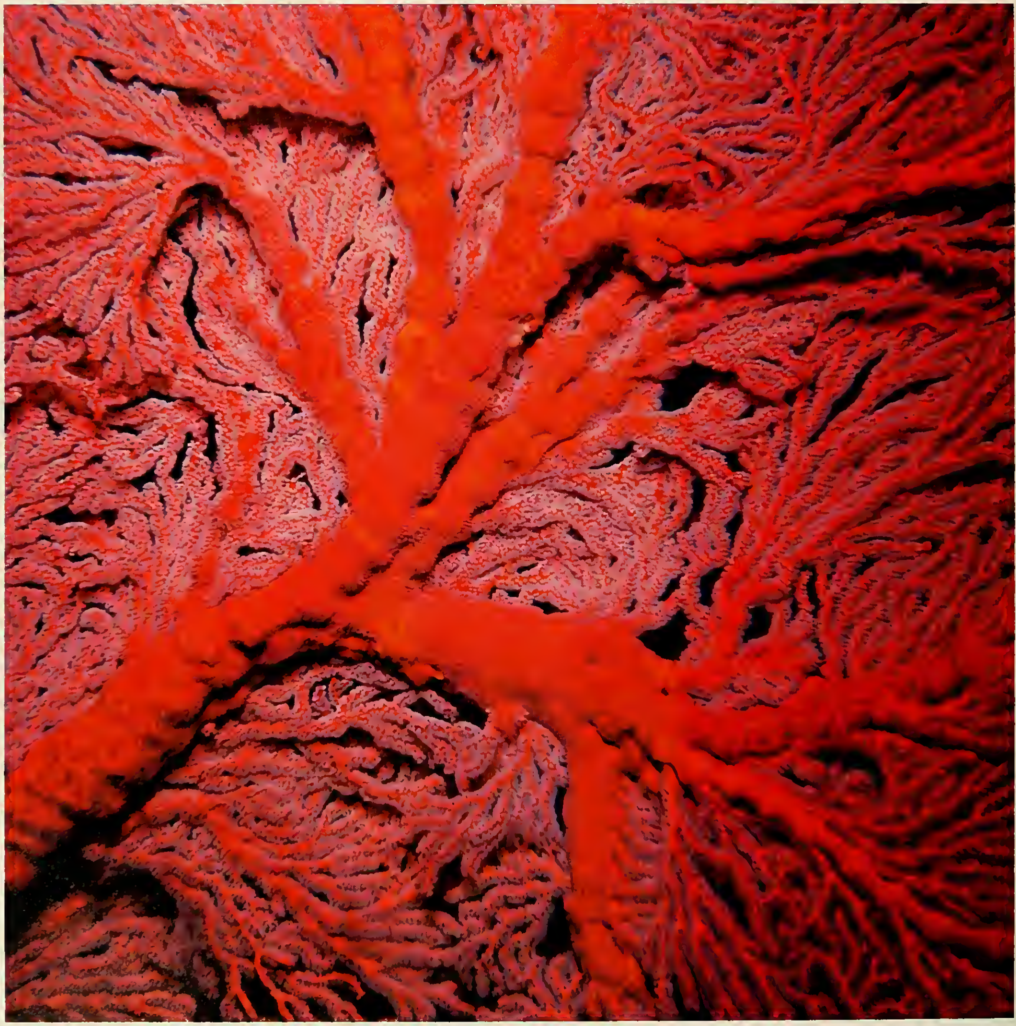
Localities of the specimens are identified by name only; no map is included. Let the reader note that "Belau," identified as the site of more than 80 percent of the pictures, is the native spelling for the Palau Islands, although reference to this nomenclature is not to be found in any map or gazetteer. Clarification of this matter is perhaps deliberately omitted. A desire for secrecy may have been engendered by the experience of the photographer, who upon returning to a favorite site, identified in a previous publication, found it stripped by collectors.

During his years of association with the underwater world of the coral reef, Douglas Faulkner gained a reverence for the life he observed there. It would be an admirable accomplishment if this feeling could be transmitted to a larger



*Maze coral* Pectinia lactuca

*Sea fan* Melithaea squamata *feeding, below, and contracted, right.*



*Tube coral* Dendrophyllia gracilis

audience, so that the general public might be equally impressed by the beauty and complexity of this portion of the environment, so often threatened by human incursion. However, this endeavor is not promoted by embroidering the obvious beauty, so effectively captured on film, with the kind of "plastic-flowery" prose favored by both authors. Consider this description of *Symphyllia recta*, the symphony coral (it has orchestrated movements): "The psychedelic concert of light on pattern is magical. Mesmerized by the pendulum tick of a metronome, I stare at a white mouse, pink nose twitching, scurrying along a cheese white line." This sounds less like a representation of any reef organism than the effects of nitrogen narcosis. Straightforward, well-crafted description would be a much more effective extension of the visual presentation.

Unfortunately, this opportunity to produce a valuable reference on the corals has not been fully realized. These days it is a rare marine biologist who does not dive and photograph, and having this collection for comparison is certainly helpful, as far as it goes. However, major elements of the fauna have been omitted, probably for lack of a sufficiently ravishing photograph. The Atlantic coral community has been especially shortchanged.

An unwieldy degree of randomness already exists in the literature and any effort to organize it should be welcomed. *Living Corals* has the raw material for a start in that direction.

*Walter H. Adey, a curator in the Department of Paleobiology at the Smithsonian Institution, has spent the past decade studying tropical reefs in the Caribbean.*

# THE FAMILY LIBRARY OF THE WORLD'S GREAT BOOKS

- *Fifty of the greatest, most enjoyable books ever written, selected by a distinguished board of advisers.*
- *In elegant, enduring bindings of fine leather and fabric, with accents of 22 karat gold.*
- *With exciting illustrations in every volume.*
- *For only $19.50 per volume—a superb family library to be enjoyed now and treasured as an heirloom in years to come.*

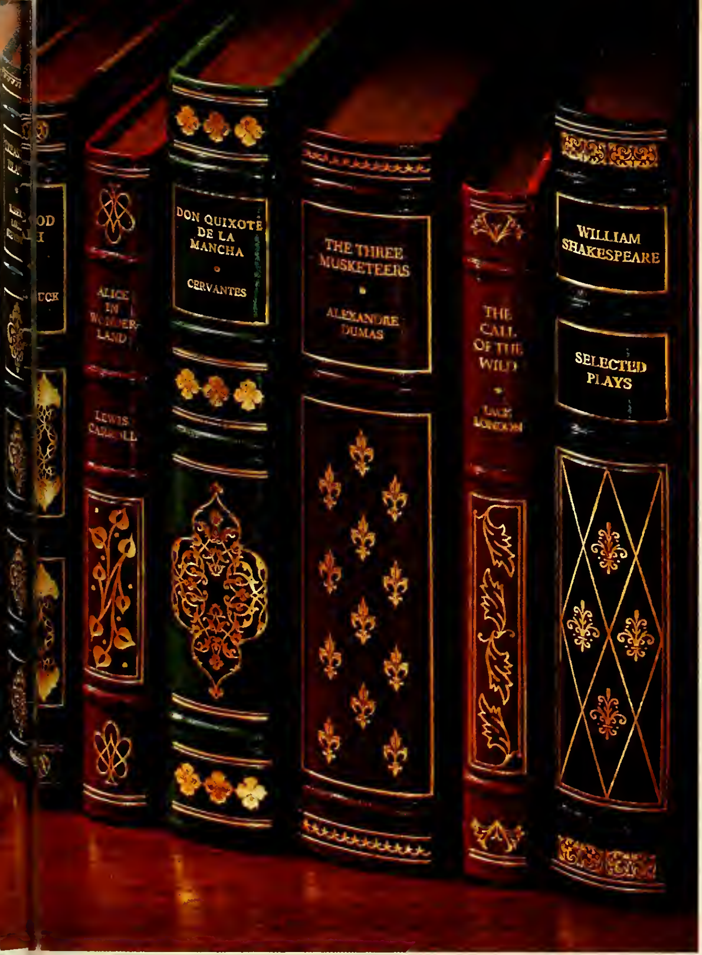
"Books are the treasured wealth of the world," wrote Thoreau—"the fit inheritance of generations." For great books have the power to enrich the mind and spirit. To expand our horizons. To make our lives more interesting. To make *us* more interesting.

Now, The Franklin Library brings you the fifty greatest, most enjoyable, most readable, most memorable classics of world literature in an edition of great and enduring beauty...at an affordable price.

These are the *universal* classics—the very core of the cultural heritage of all mankind—specially printed and bound to enhance the joy of reading, and to grace the finest homes.

The traditional English Quarter Leather binding of every volume in this edition will be a beautifully coordinated combination of leather and fine fabric. The leather will be ornamented with 22 karat gold. The fabric will be embellished with original designs. And each volume will be enriched by elegant endleaves...exciting illustrations...and fine bookpapers.

As a subscriber, the first volume you will receive will be Dickens' *David Copperfield*, one of the greatest novels



ever written. A novel whose fascinating story closely parallels Dickens' own life. "Of all my books," Dickens said, "I like this the best."

And each month thereafter, you will receive one additional book—its pages filled with the world's greatest writing. Each book a delight to read and reread, until its scenes and characters and insights—the *life* and *experience* within its pages—become the stuff of memory ...leaving you and your family forever enriched.

### Books of enduring beauty

As you open each volume and turn its pages, you will discover new delights. The decorative endpapers and bound-in ribbon page marker—carefully and tastefully color-coordinated to the book's covers. The page edges, gilded with a special tarnish-free finish, adding protection as well as beauty to each volume. Magnificent illustrations, some in full color. And the bookpaper itself, specially milled to retain its beauty for many generations.

For these luxurious volumes will be crafted to *retain* their beauty. So that this private library will be a lasting heirloom. To be treasured by you and your family now, and by your children and your children's children in years to come as "the fit inheritance of generations."

Imagine the satisfaction of glancing around your living room and seeing this treasury of great literature—the fifty beautiful volumes which make up The Family Library—the rich leather of their distinctive spines enriched by 22 karat gold ornamentation.

Imagine the pleasure of anticipation, as you slide one of the volumes from its place, open it at the bound-in ribbon marker, and begin to read. Enjoying the handsomely printed text, the fine, evocative illustrations.

And imagine, too, seeing your family immerse themselves in these challenging and enduring works of literature—and reaping all the rich rewards which that entails.

**Return your application postmarked by February 29, 1980**

*The Family Library of the World's Great Books* is being offered at this time at the attractively low price of just $19.50 per volume. But it is available at this price *only* to those who subscribe to the complete collection.

The accompanying application assures you of the *guaranteed* price of just $19.50 per volume for the entire Family Library. And you have the right to cancel your subscription at any time upon 30 days' notice, or return any book, for any reason, within 30 days. To be accepted, however, your application should be postmarked no later than February 29, 1980.

---

**THE BOARD OF ADVISERS**

RATE AND STYLE INFORMATION

$1.75 per word; 16 word ($28) minimum. *Display classified* is $150 per inch. All advertisements must be prepaid. Rates are not structured for agency or frequency discounts. All advertisements are accepted at NATURAL HISTORY's discretion. Send check/money order payable to NATURAL HISTORY to: The Market, NATURAL HISTORY Magazine, Central Park West at 79th St., New York, NY 10024. Please include your personal address and telephone number, issue preferred, and suggested heading. Deadline—8th of month, two months prior to cover date (the January issue closes Nov. 8). Camera-ready art is required for display ads. A tearsheet or copy of the page with your ad will be sent upon publication.

Box numbers, telephone numbers, and hyphenated words count as two words; abbreviations and zip codes as one word each. All states are shown in two-letter code followed by zip, then telephone (with area code), if desired. Occasionally, slight editing is required for clarity. Thank you!

# Additional Reading

**Brown Hyenas** (p. 44)

Since 1972 a long-term study has been under way of the limiting factors for the southern Kalahari's endangered brown hyena population. M.G.L. Mills, a leading contributor to this study, summarizes some of his work in "Foraging Behaviour of the Brown Hyaena (*Hyaena brunnea* Thunberg, 1820) in the Southern Kalahari" (*Zeitschrift für Tierpsychologie*, vol. 48, 1978, pp. 113–41), which is also a guide to some current literature on brown hyenas. Two other papers are J. D. Skinner's "Ecology of the Brown Hyaena (*Hyaena brunnea*) in the Transvaal with a Distribution Map for Southern Africa" (*South African Journal of Science*, vol. 72, 1976, pp. 262–69) and "The Diet of the Brown Hyaena (*Hyaena brunnea*) in the Southern Kalahari" (*Koedoe*, vol. 21, 1978, pp. 125–49), by M.G.L. Mills and M.E.J. Mills. *Hyaena*, by Hans Kruuk (New York: Oxford University Press, 1975), contains many black-and-white photographs. While mainly about foraging, hunting, competition, and social behavior of the spotted hyena, the book includes comparisons with the brown hyena. A more detailed study of the spotted hyena, written by the same author, is *The Spotted Hyena: A Study of Predation and Social Behavior* (Chicago: University of Chicago Press, 1972).

**Water Bugs** (p. 56)

Robert Smith's most recent papers on the reproductive behavior of giant water bugs include "Repeated Copulation and Sperm Precedence: Paternity Assurance for a Male Brooding Water Bug" (*Science*, vol. 205, 1979, pp. 1029–31) and "Paternity Assurance and Altered Roles in the Mating Behaviour of a Giant Water Bug, *Abedus*

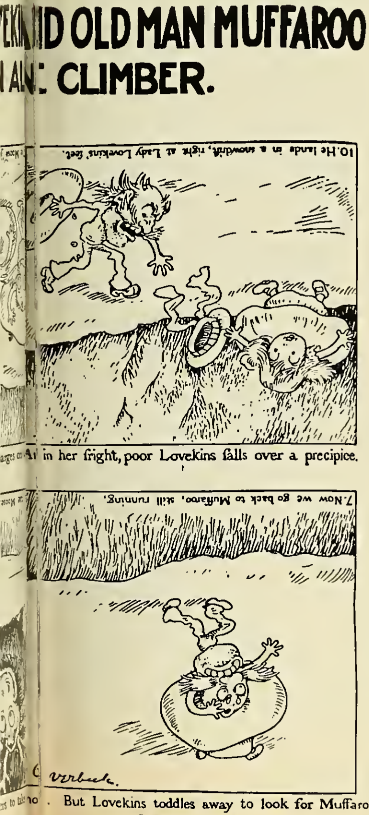
From *The Incredible Upside-Downs of Gustave Verbeek* *herberti*'' (*Animal Behaviour*, vol. 27, 1979, pp. 716–25). Robert and Janice Matthews's *Insect Behavior* (New York: John Wiley and Sons, 1978) provides entertaining and informative accounts of reproductive behavior in a variety of insect species, and *Animal Behavior: An Evolutionary Approach*, second edition, by John Alcock (Sunderland: Sinauer Associates, 1979), draws examples of behavioral principles from the entire animal kingdom. *Sex, Evolution, and Behavior: Adaptations for Reproduction*, by Martin Daly and Margo Wilson (North Scituate: Duxbury Press, 1978), discusses the evolutionary causes of sexual behavior.

### Snake Skins (p. 64)

Skin shedding in amphibians and reptiles is discussed in *The Natural History of North American Amphibians and Reptiles*, by James A. Oliver (New York: D. Van Nostrand Co., 1955). Angus D'A. Bellairs refers to shedding throughout his *Reptiles* (Atlantic Highlands: Humanities Press, 1975) and also in *The Life of Reptiles*, volume two (New York: Universe Books, 1970). *All about Snakes*, by Bessie M. Hecht (New York: Random House, 1956), is a children's book on snakes that discusses and illustrates snakes shedding their skin. A technical paper with further references is ''Histological Changes in the Epidermis of Snakes during the Sloughing Cycle,'' by P.F.A. Maderson (*Journal of Zoology*, vol. 146, no. 1, pp. 98–113).



D OLD MAN MUFFAROO
CLIMBER.
10.He lands in a snowdrift, right at Lady Lovekins feet.
in her fright, poor Lovekins falls over a precipice.
7.Now we go back to Muffaroo, still running.
Verbeek
But Lovekins toddles away to look for Muffaroo.

Gustave Verbeek in the *New York Herald*, c. 1904

### Visual Puns (p. 72)

Ernst Hans Josef Gombrich has written numerous books on art, perception, and illusion. Of particular relevance are *Art and Illusion: A Study in the Psychology of Pictorial Representation*, second edition (Princeton: Princeton University Press, 1961) and *The Story of Art* (New York: E. P. Dutton and Co., 1978). His *Illusion in Nature and Art*, coedited with R. L. Gregory (New York: Charles Scribner's Sons, 1973), has six chapters by different authors, with discussions of the science and philosophy of illusion in art and nature, and many illustrations and photographs. Ludwig Wittgenstein's elegant, influential *Tractatus Logico-Philosophicus* (Atlantic Highlands: Humanities Press, 1972) represents his early linguistic philosophy and relates logic and language in his picture theory of language. Norwood Russel Hanson discusses philosophical aspects of research and discovery and argues that the discovery of plausible scientific hypotheses is a rational procedure in his *Patterns of Discovery: An Enquiry into the Conceptual Foundations of Science* (New York: Cambridge University Press, 1969). The book includes many examples of optical illusions. An article from the November 1972 issue of *Scientific American*, ''Pictorial Perception and Culture,'' by Jan B. Deregowski, illustrates how people of different cultures perceive pictures differently. This article can also be found in *Image, Object, and Illusion: Readings from Scientific American*, with introductions by Richard Held (San Francisco: W. H. Freeman and Co., 1974).

### by Thomas D. Nicholson

**Sun and Moon** The sun moves through the stars of Capricornus in early February, enters Aquarius about midmonth, and Pisces about March 12. On February 16, a solar eclipse occurs: total in a path crossing equatorial Africa, India, and China; partial over a wide area of the rest of Africa and Asia; but not visible in North America.

The moon is just past full on February 1, reaches last-quarter on the 9th, becomes new on the 16th, and first-quarter on the 22nd. Full moon occurs again on March 1, last-quarter on the 9th, and new moon on the 16th. During February, the moon occults (covers) Regulus twice, on the 2nd and the 29th; Jupiter on the 3rd; Saturn on the 4th; and Aldebaran on the 23rd; but no occultations will be observed from North America. Apogee moon (farthest from the earth) occurs on February 4 and March 3. Perigee (nearest the earth) occurs on February 17 and March 16, both shortly after the new moon, which will enhance the effects of the spring tides each time.

**Stars and Planets** Bright planets are well located on February and March evenings. Venus appears in the west during early twilight, brightening, appearing higher, and remaining progressively later during both months. Mercury also makes a two-week appearance in the evening twilight beginning about mid-February, when it goes through a favorable easterly (evening) elongation. The best show occurs a bit later at night, however, when Jupiter, Mars, and Saturn follow Leo up the sky. The leader of the group is Regulus, the brightest star in Leo. Close behind are Jupiter and Mars, both far brighter than Regulus. Mars is about half as bright as Jupiter and a bit more yellow. Last to rise and move across the sky is Saturn, just a little brighter than Regulus. From February 1 through 4 and again from the 29th until March 3, the moon will move past these objects. For Southern Hemisphere observers, the moon will be so close that it covers Regulus, Jupiter, and Saturn in turn.

February 1–4: Watch the moon slide past Regulus, Jupiter, Mars, and Saturn. It is closest to Regulus on the night of the 1st, to Jupiter on the 2nd, to Mars on the 3rd, and to Saturn on the 4th.

February 17: Perigee moon will bring strong tides this afternoon and tonight. Binoculars may help you find Mercury, a bright, starlike object to the right of the crescent moon during evening twilight.

February 18–19: Venus is near the crescent moon on both nights. Mercury is at greatest easterly (evening) elongation on the 19th.

February 22–23: The star near the moon is Aldebaran, in Taurus.

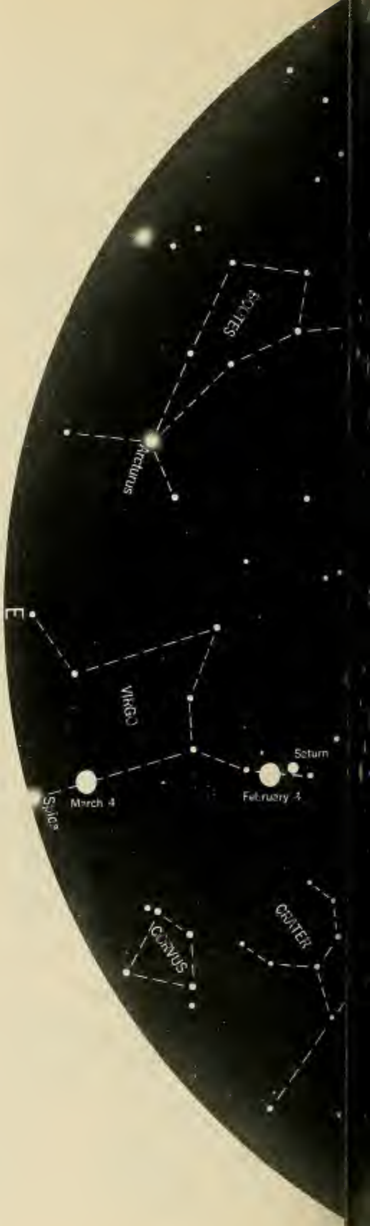
February 24–26: Jupiter is opposite the sun on the 24th, Mars on the 25th, and both become evening stars. Mars is nearest the earth on the 26th, about 62,962,000 miles distant. This is almost double its distance at a favorable opposition, when Mars becomes brighter than Jupiter.

February 29–March 3: The moon again moves past Regulus, Jupiter, Mars, and Saturn on successive days. Note, however, how the positions of the planets have changed from early February.

March 6: Mercury is at inferior conjunction, passing between the earth and the sun and entering the morning sky.

March 13: Saturn is at opposition from the sun and becomes an evening star, joining Jupiter and Mars. All three planets are now above the horizon at sunset and set before sunrise.

March 16: Perigee moon comes only two hours past the new moon, and will cause exceptionally strong tides on this and the following date.



★ Hold the Star Map so the compass direction you face is at the bottom; then match the stars in the lower half of the map with those in the sky near the horizon. The map is for 11:10 P.M. on February 1; 10:15 P.M. on February 15; 9:20 P.M. on February 29; and 8:25 P.M. on March 15; but it can also be used for an hour before and after those times.

# At the American Museum

*A curator solves homicide and missing persons cases and may be on the track of the oldest missing person of them all*

In the early 1950s, an anthropologist at the American Museum of Natural History received a telephone call from the New York City Medical Examiner's Office. They were working on a difficult missing person case and needed his expertise. Would he be kind enough to help them out?

Most Museum scientists would have been astonished to receive such a call, but for anthropologist Harry Shapiro it was all in a day's work. Since joining the Museum's staff in 1926, he had helped the police solve dozens of homicide and missing persons cases.

This particular case, the most difficult he had worked on up to that time, concerned a little girl in the South Bronx. For three days after her disappearance, the residents of the apartment building in which she lived noticed excessive heat coming from the coal-burning furnace. The police had reason to suspect that the janitor of the building had murdered the girl, so they shut down the furnace and sifted through the ashes for bones. Because the building's garbage was also burned in the furnace, the police recovered five ashcanfuls of tiny, charred bone fragments.

"They wanted me to go through the barrels," says Shapiro, "and identify any human bones. I spent days and days looking at the fragments. Of course, most of them were just bones from the dinner table. Many were impossible to identify. Finally, I found three that were undoubtably human: a fragment of the rim of the orbit [the eye socket], a finger bone, and a fragment of the pelvis. From these I was able to deduce that the person had been a young girl, perhaps ten years of age. It was enough to convict the janitor of murder."

Shapiro studied physical anthropology under Earnest Hooton at Harvard and learned to draw a variety of conclusions from human bones. By examining a skeleton, he can deduce such things as the person's sex, age, weight, height, and race. As a curator at the Museum, Shapiro has studied the genetics of diverse populations, including the descendants of the mutineers of the H.M.S. *Bounty* on Pitcairn Island, the peoples of Tahiti and the Marquesas, and the Jewish people.

He had been at the Museum only a few years when he received his first call from a despairing medical examiner. The case involved a complete skeleton that Shapiro identified with ease.

"That started it," he recalls. "Whenever they ran into human material, they would call me up." In this way, almost by accident, Shapiro became involved in the practice of forensic anthropology. During World War II, at the request of the U.S. government, he put together a set of guidelines and procedures for identifying the unknown dead. Particularly difficult cases were shipped to the Brooklyn Navy Yard, and a limousine was

**Discovery Tours**

Thirty-four Discovery Tour participants are now taking a 600-mile cruise up the Nile River, accompanied by scientists and lecturers from the American Museum of Natural History. They are visiting the temples and tombs of the past and exploring the culture of Egypt today. C. Hackforth-Jones, an Egyptologist, Niles Eldredge, a paleontologist, and John Farrand, an ornithologist, are sharing their knowledge with tour members. Their lectures range in subject from the composition of building stones and the symbolic use of local wildlife in ancient Egypt to modern Egyptian history and culture.

An identical cruise up the Nile will depart on October 19, 1980. Other Museum-sponsored cruises and trips will explore the British Isles, Mexico, Maya Mesoamerica, Morocco, Mongolia, Alaska, New Guinea, and China. For itineraries and further travel information contact Discovery Tours at the Museum.

**Element 79**

*Gold!* is the topic of this month's members' program on Wednesday, February 20, at 7:30 P.M. in the Auditorium. George Harlow, a curator in the Department of Mineral Sciences and consultant for the *It's Gold* exhibition at the Museum, will show slides and a film and discuss the history, characteristics, and uses of gold. He will explore such topics as how gold forms and where it is found and will recount some of the legends and myths surrounding this coveted metal. The free program is open only to members of the Museum.

**Old New York**

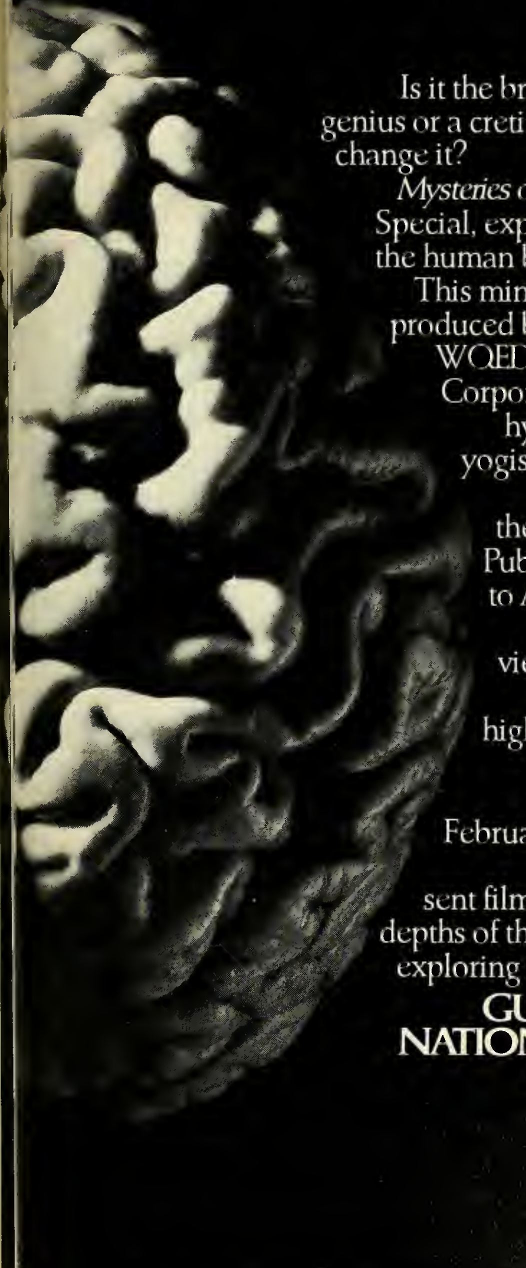
On Saturday, February 2, the Museum, in cooperation with the Archaeological Institute of America, will present an all-day symposium entitled *The Archeology of New York City*. The symposium will involve panel discussions with slide-illustrated papers. Participants include Bert Salwen, chairman and professor of anthropology at New York University, Nan Rothschild, professor of anthropology at Hunter College, and Robert Schuyler, professor of historic anthropology, University of Pennsylvania. The symposium will last from 10:00 A.M. to 4:45 P.M. in the Auditorium and is open to all Museum visitors. There is no admission charge.

**Kora Concert**

In celebration of Black History Month, Alhaji Bai Konte and Dembo Konte will present a musical interpretation of African folklore on Sunday, February 17, at 2:00 P.M. in the Auditorium. The program is free to Museum visitors. Bai Konte and his son Dembo will play the *kora*, a 21-stringed instrument of West Africa, which sounds like a cross between a guitar and harpsichord. The *kora* is the "KO" that helped to reunite the Kinte and Haley family branches of "Roots" fame. The Kontes are oral historians and balladeers, called *griots*, who keep alive the traditions and genealogies of the Mandinka people of West Africa. The program is sponsored by the Museum's Department of Education.

**Body Language**

Slim Goodbody will present the February members' family program on Sunday, February 24, at 2:00 P.M. in the Auditorium. Sporting his "body suit," with its drawings of internal organs, he will regale children with facts and stories about the human body—how it works and how to make it work better. The program is free to members; nonmembers may purchase tickets for $2.50 at the door.



Is it the brain of a killer or a saint? The mind of a genius or a cretin? Is there any way to tell? Any way to change it?

*Mysteries of the Mind*, a new National Geographic Special, explores the most powerful force on earth, the human brain.

This mind-expanding hour for the entire family, produced by the National Geographic Society and WQED/Pittsburgh with a grant from Gulf Oil Corporation, looks at pain control, sleep, and hypnosis research in America, as well as yogis in India, and acupuncture in China.

Gulf made a commitment with the National Geographic Society and the Public Broadcasting Service five years ago to American-made Public Television.

Together, we've set Public Television viewing records.

In fact, the shows are consistently the highest-rated specials on PBS.

For an hour of discovery television, remember the first Monday of January, February, March, and April.

And enjoy great television that has sent film crews around the world, diving to the depths of the ocean, digging into new worlds, and exploring the most powerful force on earth.

BEAT INFLATION
OWN NUMISMATIC
SILVER DOLLARS

Numismatic uncirculated coins have actually outperformed every type of investment for the past 20 years. Silver coins from America's historic past in brilliant uncirculated condition consistently increase in value 20% or more every year.

In 1970, a paper and a silver dollar each bought 3 gallons of gas. Only 9 years later, a paper dollar hardly gets you 1 gallon but a numismatic uncirculated silver dollar could buy you a few tankfuls.

People in the know are investing a good part of their savings in collectables of all types, numismatic coins are the no. 1 choice. For free brochure and details, call our 24 hr. toll free number.

ered in China, nothing approaching the completeness of the first bones has ever been found.

Shapiro was a graduate student when the fossils were unearthed in the 1920s. Early hominid fossils were rare then, and he recalls that the discovery made a sensation. Later, in 1931, while doing research in China, he met Davidson Black, who was working with the fossils at Peking Union Medical College. Black let Shapiro examine the fossils himself.

"Black died in 1933," Shapiro recalls, "and was replaced by a famous German anatomist, Franz Weidenreich. By the summer of '41 things were looking bad, so Weidenreich left China and came to New York [leaving the fossils behind]. His lab is now the staff room of the Museum. We became very close friends. I remember one day he came in to me in great despair. The fossils had disappeared."

AMNH

*The skull of Peking man, created from plaster casts of the fossils at the American Museum.*

An almost complete lack of hard information surrounded the disappearance until 1971, when Shapiro was contacted by William T. Foley, a prominent New York heart specialist. Foley had been a medical officer in the United States Marine Corps stationed in Tianjin in 1941, and he gave Shapiro some new information about the fossils. In November 1971 Shapiro wrote an article for *Natural History* in which he recounted Foley's story ("The Strange Unfinished Saga of Peking Man").

The article made front-page news across the country and reopened the search for the fossils. Six months later, Shapiro got a call from Christopher Janus, a travel agent who had just returned from China. The director of a

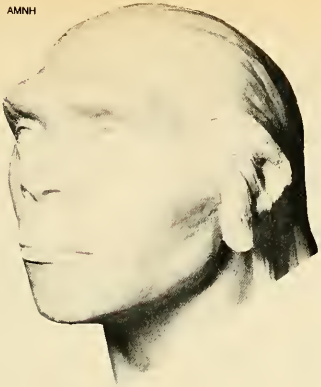
AMNH



*A reconstruction by Franz Weidenreich of what Peking man probably looked like.*

new museum at Zhou Guodian (where *Sinanthropus* had been found) had gotten hold of the *Natural History* article and was tremendously excited. He urged Janus to do all he could to recover the fossils for China.

Janus returned to the States and immediately posted a $5,000 reward for information leading to the recovery of Peking man. Shapiro and Janus worked together following up many leads—mostly spurious.

"A strange story with an offer of reward is bound to attract, shall we say, imaginative people," admits Shapiro. "There was a story about the bones in a cabin high in the California hills, and so on. We even had one countess living in New Jersey who claimed she had the fossils. It's been one damn thing after another."

In 1974, Shapiro wrote *Peking Man*, a book about the fossils and their disappearance. The book concludes: "This is a tragic end that I am not yet prepared to accept until every clue has been explored and pursued."

Just recently, a new—and perhaps vital—clue has surfaced. If the information is correct, Shapiro explains, then he knows where the fossils are buried in China. "I'm reluctant to discuss it now because I'm still negotiating with the Chinese about it. It may very well turn out to be nothing, like so many other leads. I'm simply asking 'let's look into it.' Of course, I will investigate this only with the complete knowledge and cooperation of the Chinese. After all, the fossils are theirs."

# Moses and Manhasset

*Why would modern Jews maintain a kosher home in America?*

When Solomon Carvalho explored the Rocky Mountains in 1853 as the daguerrotypist on John Charles Frémont's last expedition, this Jewish adventurer did not obey the dietary laws of his religion. He ate horsemeat and mule. Similarly, Sigmund Schlesinger found no ritually pure butcher shop after he survived the Battle of Beecher Island, Colorado, in 1868, when he and fifty other scouts held off 700 Cheyenne and Sioux Indians for nine days. "Killt a Coyote & eat him all up," he wrote in his diary.

Many other Jewish immigrants ate nonkosher food in America with far less justification than Carvalho or Schlesinger. Indeed, for some refugees from Eastern European *shtetlach*, one of the attractions of America was the chance it offered to throw off the constraints of kashrus, the elaborate system of biblically based food customs and prohibitions that had been mandatory in the pious homes of their parents. My paternal grandfather emigrated to Utah in search of a secular utopia on homestead land in an agrarian commune.

Thousands of other immigrants did continue to maintain kosher homes in America. But even the Lower East Side of Manhattan, in its Jewish heyday before World War I, did not provide the same isolation as Russia's Pale of Settlement, where orthodox Jewish practice had flourished undisturbed except by czarist pogroms and oppression. One of my mother's grandfathers, a rabbi with the highest standards of talmudic observance, refused to follow his congregation to New York, convinced that the holy life was impossible there. Because of Hitler, we will never know whether he and millions of other exterminated traditional European Jews would have continued eschewing pork, separating meat and milk in the same meal, and otherwise eating orthodox Judaism's idea of pure food had they made it to the United States.

Statistically speaking, my great-grandfather's fear has been borne out by history. Given ample opportunities to assimilate into the American diet, millions of American Jews have done so. Even among those affiliated with Jewish congregations, the majority (1.1 million families) are Reform Jews who are not required to keep kosher homes. Orthodox and Conservative congregations, which officially demand the observance of kashrus, claim at least 775,000 families. These figures leave out Jews with no formal synagogue membership, most of whom presumably do not adhere to dietary tradition. Obviously, then, kosher keeping has declined. But surely more remarkable in this era of conspicuous consumption and intermarriage is that more than three-quarters of a million American households still profess allegiance to the spiritual and practical ideal of maintaining a kosher home. Indeed, some American Jews raised without any kosher principles are now converting their lives and homes to kosher practice.

Zelda and Irving Leibowitz, who live in the New York suburb of Manhasset Hills, raised their five children in a nonkosher home. Although they belong to a Conservative synagogue, their only nod to kashrus until recently had been to avoid bringing *trayf* (nonkosher foods such as pork and shellfish) into the house. Then they went with a group from their synagogue to a weekend retreat in Morristown, New Jersey, a sort of conference sponsored by the Lubavitcher hasidim, a sect of Orthodox Jews very active in wooing less observant Jews back to strict forms of piety.

"I was very impressed," says Zelda Leibowitz. "I wanted something more than Conservative Judaism."

At the retreat she learned that the Lubavitcher Women's Organization was ready to help her kosher her home. Late last year, Mrs. Leibowitz, with the support of her husband, embarked on a strenuous process that turned her kitchen upside down and completely changed her life and that of her family.

Lubavitcher representatives went through every cabinet and closet, eliminating all foodstuffs not stamped with a seal of rabbinical approval. They scrubbed her countertops and rinsed her pots with boiling water. Men took the metal pots and pans outside behind the house and burned them with a blowtorch to remove any lingering traces of food. They also took the pots in cartons to a ritual bath in Brooklyn for consecration. Unfortunately, utensils made of earthenware, glazed china, Pyrex, or Corning Ware cannot be koshered, and Mrs. Leibowitz had to give them all away. When I visited her, she was using paper plates and intending to replace her china with two new sets: one for meat dishes, the other for dairy foods.

Like all kosher principles, the separation of meat and milk is the result of divine ordinance enunciated in scripture and interpreted by rabbis over the centuries. The basic idea sounds simple, but it has ramified into a system of daunting practical complexity. To keep meat and dairy products from

Dear Friend of Great Music,

To acquaint you with the Society's musical fare and recording program, we'd like to send you an outstanding record that has captivated thousands of Americans FOR ONLY $1.00!

It is rare that a recording is made that is truly "out of this world" with the ethereal qualities of music, performance and sonics ideally presented. But this recording is, indeed, OTW, embodying all these characteristics!

The Society is happy to offer a recording of such captivating power that Hamlin's story of the Pied Piper pales! All who hear this recording simply MUST have it and go to great lengths to get it. When radio stations play this recording, their phones are tied up for hours. A New York City station had more than 400 calls when they played this recording! A San Francisco station had a similar experience.

While this recording is enrapturing and delightful throughout, the first work, CANON IN D MAJOR, is so mesmerizing that hearers are overcome. Your writer was so hypnotized that I spent well over an hour repeating the first work before I even bothered to go to the others when I first listened to the record!

But the other works are transporting as well. The performance of the orchestra could not possibly be excelled and the trumpet playing is so spectacular that it is, in a word, breathtaking!

Certainly you'll treasure this recording as your favorite. You'll insist that all your friends hear it in the confidence that they will be grateful that you have introduced them to such a "revelation" in music.

### GET THE SOCIETY'S CATALOG FREE!

With your introductory record, the Society will include its catalog of about 3,000 recordings.

Musical Heritage Society issues each year about 200 new recordings of the music of such great masters as Albinoni, the Bachs, Beethoven, Berlioz, Buxtehude, Charpentier, Corelli, Couperin, Gluck, Handel, Haydn, Lully, Monteverdi, Mozart, Pergolesi, Purcell, Scarlatti, Schubert, Telemann, Torelli, Vivaldi, and many others. Its recordings cover all musical periods: Medieval, Renaissance, Baroque, Rococo, Classical, Romantic, and Modern. Over 200 of its recordings have been honored with the coveted GRAND PRIX DU DISQUE and other international awards.

### MUSIC THAT CAPTIVATES!

Even though the Society's records are of serious music, it has some that are "hits!"

Take MHS 1100 in our catalog, for instance. When it was played over a pops radio station frequently for a short period of time, over 80,000 records were sold as a result!

Or consider the Society's MHS 1060. This record, when played by radio stations, results in an avalanche of calls that tie up their switchboard for hours afterwards!

From among the Society's 3,000 records there must be many that will captivate you

### THE LARGEST RECORDING PROJECTS IN HISTORY HAVE BEEN ACCOMPLISHED BY THE MUSICAL HERITAGE SOCIETY!

The Society's recording feats are the sensation of the record industry! These are some of our notable accomplishments:

- The Society was the first to issue all 107 of HAYDN'S Symphonies. They are on 49 records (MHS 201 through MHS 249).
- The Society has issued on 25 records ALL that BACH composed for Organ.
- The Society has issued many complete works: ALL the Sonatas, Quartets, Symphonies of BEETHOVEN; ALL MOZART'S Piano Concertos and Quartets; ALL of SCHUMANN'S solo Piano Works; ALL of DEBUSSY's and RAVEL's solo Piano Works and much more!

Most of the Society's records are of works recorded FOR THE FIRST TIME! Manufactured to the highest quality standards of which the recording industry is capable, the Society's records are perhaps the finest in the country.

### HOW THE SOCIETY OPERATES

The Society's recordings are not sold in stores. They are offered directly through the MUSICAL HERITAGE REVIEW magazine at 3 week intervals (18 times a year). As a member, you'll enjoy substantial savings. Member prices are $3.95 per LP and $4.95 per cassette, plus postage and handling.

When the Society receives your request, it sets up an account in your name and will begin sending your free one-year subscription to MUSICAL HERITAGE REVIEW for your edification and delight. There is NO PURCHASE OBLIGATION and you may discontinue the complimentary subscription at any time. As a subscriber 2 (sometimes 3) outstanding selections will be scheduled for shipment to you from each issue--but there is no obligation to accept them . . . order only those you want when you want them!

A special response form will be enclosed with each Review . . . and you may use it to order or reject any selections simply by mailing it by the date specified And if you want only the scheduled selections, you need do nothing-they will be shipped to you automatically. What's more, you'll have at least 10 full days in which to make your decision--if you ever have less time than that, just return the special selections at our expense, for full credit.

### ONE OF THE TRULY GREAT RECORDINGS OF THIS DECADE! "A REVELATION IN MUSIC!"

To receive this splendid record, simply mail the request form provided below along with $1.00. We're confident that you'll so treasure this trial disc that you'll be moved to acquire more of the Society's fine recordings.

It would be a privilege and pleasure to serve you.

contaminating each other, Mrs. Leibowitz divided her kitchen down the middle—with one side reserved for meat, the other for dairy—and installed a second sink for her dairy dishes. Meat utensils are tagged with red tape, dairy with blue. She has kosher kitchen soaps, also in red and blue. She is not using her dishwasher pending expert advice on whether it can be salvaged. Many Orthodox Jews have two dishwashers to eliminate any doubt about milk-meat contamination through a common machine.

The principle of meat-milk separation also introduces complications into cooking and eating. A serious kosher keeper does not want his body contaminated by internal mixing of meat and milk in the digestive tract, so he eats no dairy products for six hours after eating meat. After a dairy meal, on the other hand, the wait before eating meat can be much shorter, unless one has eaten a hard, aged cheese.

Then there is the basic question of which raw materials and basic food products are kosher and which are not. Kosher meat comes only from animals that have cloven hoofs, that chew their cud, and that have been properly slaughtered. Ritual slaughter—slitting the throat swiftly with a knife—must be performed by specially trained people under strict rabbinic supervision, and about half of each animal cannot be used. Hindquarters are not kosher, because the forbidden sciatic nerve is too deeply embedded in the muscle tissue to be removed except with great difficulty. Ergo, sirloin steaks are *trayf*. So is forequarter meat from an animal with internal defects such as adhesions on its lungs. And even bona fide kosher meat has to be rinsed and salted (see recipe) or broiled, sometimes both, to extract the blood, a forbidden substance.

These requirements are only the most basic of the koshering rules for meat. The average person in modern society is simply not in a position to comply with all the provisions. As a result, it is commonplace to rely on kosher butchers. Mrs. Leibowitz goes to one near the Lubavitcher headquarters in Crown Heights, Brooklyn.

When it comes to seafood, she faces an entirely different set of perplexities. To be kosher, seafood must possess both fins and scales. (Clearly, this means that lobster and shrimp and clams are taboo.) But a kosher fish scale is special: it must be easily removable and has to form a separate integument on top of the fish's skin. Mrs. Leibowitz must therefore be able to distinguish between species of fish with kosher scales, and others (eels, swordfish, sturgeon, and catfish) with no scales or scales that are embedded in the flesh. For guidance, she can turn to a handlist of fish prepared for the Union of Orthodox Jewish Congregations of America by James W. Atz, curator and Dean bibliographer in the Department of Ichthyology of the American Museum of Natural History.

Mrs. Leibowitz and other strict kosher keepers also have to be particularly concerned about packaged foods and food additives. In effect, they depend on the judgment of professional kashrus supervisors who work for food manufacturers. These experts have to judge the kosherness of chemicals undreamed of by the authors of the Talmud, and they are not without their critics.

"Kashrus supervision has become 'big business' with big business practices," wrote Rabbi M.D. Tendler, faculty advisor to a student group at New York's Yeshiva University, which has published a brief *Guide to Kashrus*. Rabbi Tendler, in his introduction to the pamphlet, sounds like a Hebraic Ralph Nader campaigning for truth-in-labeling: "The secret process, the half-truth or actual misleading information, and the privileged information clauses written into kashrus-supervising contracts forbidding manufacturers from even answering questions related to the kashrus of their products, are . . . alien to our Torah community and rejected even by our secular society which now emphasizes the 'right of the consumer to know.'"

For her part, Zelda Leibowitz looks for the seals of rabbinic approval on packaged foods without puzzling over what Rabbi Tendler calls "the interface of food technology and kashrus laws." But even this much scrutiny adds to the special labor of her kosher shopping in modern America.

Why go through all this? What reason did the Lubavitcher hasidim give Mrs. Leibowitz that could possibly justify the daily contortions of kashrus? "No rational explanation is given in the Torah," says the author of the Lubavitcher Women's Organization's cookbook. The rules of kashrus produce health only as a "fringe benefit," but the text continues, "we observe them because they are the will of G-d and were given to us for all time at Mt. Sinai."

As a practical matter, however, the elaborate ritual of kashrus sets Jews apart from non-Jews, makes it virtually impossible for them to eat comfortably with Gentiles. By the very arduousness of its requirements, kashrus encourages the preservation of a separate Jewish identity in a non-Jewish world. To worry if a cheese was coagulated with kosher rennet is to affirm one's Jewish identity in a small but profoundly unambiguous way.

### Chopped Liver

(Adapted from *The Spice and Spirit of Kosher-Jewish Cooking*, published by the Lubavitcher Women's Organization, 770 Eastern Parkway, Brooklyn, N.Y. 11213)

1 pound beef liver
Coarse kosher salt
3 eggs, hard-boiled
1 large onion, peeled and chopped
2 tablespoons oil
½ teaspoon salt
¼ teaspoon pepper
1 tablespoon lemon juice (optional)
½ tablespoon mustard (optional)

1. Since liver has too much blood in it for salt alone to do an effective job of koshering, it is not salted in the regular way. It is salted on all sides (with coarse kosher salt) and also must be roasted over an open fire or over the open flame of a gas range (not an electric fire). If roasting a whole beef liver, cut into it across its length and width before roasting. Thoroughly wash off all outside blood and remove all visible blood clots. Salt the liver immediately before the roasting. Roast over an open fire with nothing between the fire and liver so that the blood can flow out freely. A thin wire net with large holes may be used to hold the liver over the fire. Rotate the liver a few times, so that all sides will be exposed to the fire and become roasted. If you use an open fire from a gas range, cover all sides around the open fire so that no blood can splash on the stove and render it unkosher.
2. Grind liver, eggs, and onion. (For added flavor you can sauté onion in oil first.)
3. Mix together well.
4. Add oil and seasoning and mix again.

# MEETING THE DEMANDS OF SOCIETY IS NO EXCUSE FOR BUILDING A BORING CAR.

If one accepts the dismal prophecies emanating from the automotive community, it appears we are destined to suffer a generation of thoroughly boring automobiles.

Cars so utterly debilitated by societal necessities, safety regulations and anti-pollution paraphernalia that they no longer will be the least bit interesting to drive.

All this pessimistic doomsaying, however, neglects to take into account the obsessive determination of the engineers at BMW in Munich, Germany to build extraordinary automobiles.

Against all odds, the BMW 528i not only satisfies the laws of the land and the demands of the gas tank, it does so without ever once violating our conviction that extraordinary performance is the one rational justification for owning an expensive car.

### FEW CARS PERFORMED THIS WELL BEFORE POLLUTION CONTROLS.

"Expensive sedans," writes Car and Driver magazine, "tend to ride like pillows when you cruise them and squeal like pigs when you push them."

A bit caustic perhaps.

But, an analysis that makes the performance statistics of the BMW 528i seem all the more remarkable.

Round a particularly hair-raising curve and the legendary BMW suspension system—independent on all four wheels—flexes with a resiliency that makes one feel as if the car were built into the roadway.

Press the accelerator and the 528i's fuel-injected, 2.8-liter, overhead cam engine responds in a manner that can only be described as exhilarating—even by pre-pollution control standards.

Yet, the BMW 528i (with 5-speed standard transmission) delivers 18 EPA estimated mpg, 30 estimated highway mileage and, based on these figures, an mpg range of 295 miles and a highway range of 492 miles.

(Naturally, our fuel efficiency figures are for comparison purposes only. Your actual mileage and range may vary, depending on speed, weather and trip length. Your actual highway mileage and highway range will most likely be lower.)

### LUXURY NEEDN'T BE MERELY A FACADE.

One's taste for luxury would have to be insatiable indeed to imagine an appointment or convenience lacking in the 528i.

AM/FM stereo cassette, full-power accessories, air conditioning, and the like, are all standard equipment.

Yet each and every facet has been strategically engineered to help eliminate the enormous strains of driving.

Its seats are anatomically shaped buckets. Its front seats are so thoroughly adjustable that it is all but impossible not to find a comfortable driving position.

All in all, in a time of lowered automotive expectations, amidst increasing mediocrity, the engineers at BMW have actually improved the BMW 528i.

If you find the notion of owning such a car more than a little intriguing, we suggest you phone your nearest BMW dealer and he will arrange a thorough test drive for you.

A RECORD OF PERFECTION

Nothing in the world of competitive sport can match the Olympic challenge. It is a challenge that demands not only the best in human athletic achievement, but a determination that can be summoned up to overcome seemingly impossible obstacles. Yet with all the talent, skill and dreams the Olympic Games focus into crystal clarity for a brief instant, there can be only a few who wear the gold.

For Peggy Fleming and Jean-Claude Killy, the intensity of their gold-medal winning performances on the ice and slopes passed through them for a few moments of heart-stopping action most of us never feel in a lifetime. But the memories of the day live for them forever. In photographs.

Canon is proud to be the Official 35mm Camera of the 1980 Olympic Winter Games. Under conditions of utmost severity, in a situation that decries compromise, Canon photographic equipment will be there to help deliver images that are as good as humanly possible.

We'll be at the Games supporting professional photographers with service and repair, systems support and supplementary or emergency equipment. Standing behind our commitment to outstanding photography by offering the best assistance money, skill and dedication can offer.

But the Olympic Games are just one way we try to prove our commitment. It's also in every Canon product you buy. Proving itself in every kind of shooting situation. It's a quality standard that goes deeper than the name on the pentaprism, the difference between Canon cameras and others that seem to offer equivalent performance. And it's something that just can't be faked.

It's natural that when you think about the Olympics, you think about superlatives. At Canon, we don't use superlatives lightly. We want to be the best we *can* be.

And we know you do, too.

# NATURAL HISTORY

MARCH 1980 • $1.50

# OLD VOLVOS NEVER DIE. THEY PASS ON.

When it comes to cars, the good don't die young. And Volvos are so well-made they seem to go on forever. (The current life expectancy of a Volvo is now up to 17.9 years in Sweden.)

Witness the case of William Moser, a broadcast engineer. Over the years he's bought five Volvos and they're all still in the family. You see, instead of trading in his old Volvo every time he wants a new one, he passes it on to a member of his family. Because he believes his family is better off in a used Volvo than in any new car.

According to Mr. Moser, "Every time I get a new Volvo, my family is as excited about it as I am. After all, they know someday it'll be theirs."

So if you're tired of buying cars you run into the ground in no time, do as Mr. Moser did. Buy a car that could run in the family for years.

**VOLVO**
A car you can believe in.

Bill Moser with his new Volvo. And his family with his old ones.

# Authors

**Michael Aris** encountered Bhutan's tradition of sacred dance during his five years' residence in the country, where he occupied the posts of tutor to the royal family and head of the translation department. He has made field trips with his Burmese wife and two sons to Sikkim, Nepal, and northern India. Currently research fellow in oriental studies at St. John's College, Oxford, Aris's major interest is Tibetan and Himalayan history and culture. In 1979 he convened in Oxford the International Seminar on Tibetan Studies. His forthcoming book, *Bhutan: The Early History of a Himalayan Kingdom*, is based on his Ph.D. dissertation for the University of London.

Curator of the department of herpetology of the Atlanta Zoological Society, **R. Howard Hunt** has done much of his research on the ecology and ethology of spiders. In addition to his work on the relationship between tarantulas and narrow-mouthed toads, he is studying the trapdoor spider and the black widow. He writes that he "occasionally finds the sight and sound of humans repugnant and seeks relief spelunking and rappelling in the mountains of north Georgia." Hunt also fancies himself a writer of horror short stories.

In order to observe a mule deer buck's behavior, **Valerius Geist** has tagged along for hours as the animal ambled through the woods. His knowledge of deer and their habitat has made such fieldwork almost routine. Born in the USSR, Geist, now professor and associate dean of the Faculty of Environmental Design at the University of Calgary in Canada, has made a specialty of ungulate ecology. Commenting on his avocations and diversions, he says that his "hobbies, daydreaming, research, and teachings are not easily separated." He enjoys gardening, cooking, wine, and "arguing until there is no one left to discuss a subject with."

**Mary A. McWhinnie** started working in Antarctica in 1963 aboard the research vessel *Eltanin*. After several cruises, she began investigating the metabolic adaptations of antarctic crustaceans in order to discover how they carry on their life functions in such a frigid environment. During that study, McWhinnie spent an entire year at McMurdo Station, becoming the first woman scientist to winter over in Antarctica. In 1975, she shifted her base of operations from McMurdo to Palmer Station, where she initiated intensive research on the biology of krill. She designed large flow-through seawater aquariums, now at Palmer, which have made possible the long-term captive maintenance of krill with consequent breakthroughs in the understanding of the crustacean's biology. Altogether, McWhinnie has been to Antarctica ten times. When not on that ice-bound continent, she is a professor of biological sciences at DePaul University in Chicago.

After working for several years in dult education, coauthor **Charlene J. Denys** returned to her first love, biolgy, and is currently in the doctoral rogram of the Biology Department at DePaul. She has been working with McWhinnie, her adviser, for the past ve years and has made four research ips to Antarctica. During her first seaon there in 1975, she became intersted in the swarming behavior of krill nd the possible role of vision and bioiminescence in keeping the animals in eir characteristic aggregations. "The eer beauty of their luminescent dislays," she says, undoubtedly contribted to that interest. Denys will spend he upcoming antarctic austral season tudying krill vision. She adds that 'considering what it takes to get to and rom Antarctica, I am lucky that travelng is my favorite avocation."

Q. What is the WEBSTER'S NEW UNABRIDGED 20TH CENTURY DICTIONARY about?

WEBSTER'S
NEW TWENTIETH CENTURY
DICTIONARY
UNABRIDGED
SECOND EDITION—DELUXE COLOR
COLLINS WORLD
PUBLISHED AT
~~$59.95~~
YOUR PRICE
$19.95

A. It's about 2,300 pages and more than 4 inches thick!

For more than 40 years Webster's Unabridged Dictionary has served as an invaluable reference for students, teachers, businessmen, secretaries . . . and workers in all trades and professions. The reason is simple. Here is a dictionary that supplies the need for accurate and full definitions, correct spellings and pronunciations, full etymologies, synonyms, as well as other general and specific information.

A large staff of lexicographers and linguists has painstakingly edited and updated each definition so that it is clear, accurate, and readily understood in all its senses. Many new entries have been added, including recent additions to the language in the natural and social sciences, the humanities and other specialized branches of human knowledge.

**un·a·bridġed′**, *a.* not shortened; complete; specifically, designating a dictionary that has not been abridged from a larger work.
**un·aç·cent′ed**, *a.* not accented; specifically, in

The large, clear, legible type shown above (actual size) "makes this unabridged dictionary the most readable one in print."

**...now own one of the finest reference books in the world at only ⅓ of its originally published price.**

# The Slow Comeback of Gardiner's Ospreys

Dennis Puleston

Gardiner's Island in the 1930s and 1940s had perhaps the greatest concentration of nesting ospreys in the world—an estimated 300 nests producing about two young each. When spraying of DDT began on neighboring Long Island in the late 1940s, the osprey population plummeted. By 1965 there were less than sixty nests on the island and only four young were fledged. Thin-shelled eggs, a characteristic sign of DDT ingestion by birds, showed concentrations of more than 13 parts per million of the insecticide.

The spraying was finally stopped in the mid-1960s. And, as Dennis Puleston wrote in "Return of the Osprey" (February 1975), the birds began to make a slow recovery. By 1974, a total of twenty-six young were fledged from thirty-four active nests, and one unhatched egg showed only 3.59 ppm of DDT.

Since then, Puleston reports, the recovery has continued, with a minor setback in 1979 because of cold weather and rain when the young were hatching. In the two previous years the reproductive rate crept over one bird per nest for the first time since the mid-1950s. In both years there were thirty nests. Thirty-one young were fledged in 1977 and thirty-four in 1978. (Last year twenty-six young were fledged from twenty-six nests.) Another encouraging sign is that an unhatched egg in 1978 showed less than one ppm of DDT.

## The Difficulty of Staying Frozen

Having one's body kept intact at 320 degrees below zero might seem cold comfort to most of us. But for some people suspension (after death) in a large thermos filled with liquid nitrogen offers the hope of being brought back to life, or cloned into a surrogate second life, at some future time when the powers of science have grown.

In December 1971 *Natural History* reported on the case for and against cryonic suspension ("Immortality and the Freezing of Human Bodies"). At that time thirteen people had been frozen and were staying frozen in the United States. Their numbers have not increased.

Last fall, Art Quaife, who runs the only commercial cryonic suspension operation in the country, Trans Time, Inc., in Berkeley, California, had seven "patients" in cold storage. Curtis Henderson, who describes himself as the sole surviving member of the Cryonics Society of New York (the others didn't die, they moved to California), said he believed there was probably only one other body in the country that was being kept in liquid nitrogen.

What happened to the others? Apparently, they've been thawed, al-

# The 80th-Anniversary Natural History Photographic Competition Closes April 1

To celebrate its eightieth year of publication, and to entice you to submit your best photographs, *Natural History* has put together a bountiful package of awards for the winners of this year's photographic competition.

The Grand Prize-winner of the 80th-Anniversary *Natural History* Photographic Competition will be invited to join the American Museum of Natural History's two-week cruise around Britain and Ireland in July. This $3,000-plus prize includes air fare from New York and accommodations on the luxury cruise ship *Orpheus*.

The itinerary includes London, Southampton, Dover, Edinburgh, the Shetland Islands, Loch Ewe, Galway, Holyhead, and Guernsey, with land excursions to Canterbury, Hadrian's Wall, Holy Cross, and spectacular natural settings.

Thomas D. Nicholson, director of the American Museum and astronomer, and six other scholars will introduce travelers to the archeological, historical, and natural treasures along the route.

The 80th-anniversary competition also will award seventeen cash prizes totaling $3,500. The winning entries will be published in the July issue of *Natural History* and exhibited at the American Museum of Natural History.

First prizes of $500 each will be awarded in three major categories: The Human Family; Animals (including birds and bugs); and Plants and Their Environment. Merit Awards of $250 each will go to the best entries in four categories: Photomicrography; A Sequence in Nature (up to five photographs); Urban Wildlife; and Humor in Nature. Ten Honorable Mentions of $100 each will be selected from all entries.

Competitors may submit up to five entries in the competition.

The deadline is April 1, 1980. Please put your name and address on every entry and include a stamped, self-addressed envelope—since we want to return your pictures to you.

And good luck!

## THE RULES

1. The competition is open to everyone except employees of the American Museum and their kin.
2. Competitors may submit up to five previously unpublished entries (a sequence is considered a single entry).
3. The Museum acquires the right to publish, exhibit, and use for promotion the winning photographs. The Museum assumes no responsibility for other entries.
4. Entries may be transparencies or prints, either color or black and white, up to 8 by 10 inches. Each must bear the photographer's name and address.
5. Enclose a self-addressed, stamped envelope for the return of entries.
6. Entries must be postmarked no later than April 1, 1980.

Pack them carefully and mail them to:

Natural History Photographic
Competition
11 West 77th Street
New York, New York 10024

though Henderson and Quaife said they knew of no central source of information on who is frozen where. Henderson did point out that unless you can set up a trust for perpetual maintenance in a frozen condition, you have to rely on the good will of your descendants, a risky proposition considering the cost of cryonic suspension. In 1971 it cost as much as $8,500 to be frozen and $1,000 a year to stay frozen. Inflation has, of course, changed those figures. At Trans Time, the cost is now $12,000 to start and $2,000 a year after that. If posterity gets cold feet, an untimely thaw may be in the offing.

## A Historic Place, Underwater

In January of 1781 the British warship *Culloden*, carrying seventy-four guns, ran aground off Long Island's Montauk Point (not far from Gardiner's Island). The British spent three weeks stripping the ship and then burned her to the waterline to prevent the colonists from salvaging anything from her. Nonetheless, unruly Americans managed to get some of the ship's iron and copper before she disappeared from view.

In 1971 Henry W. Moeller (coauthor with Steven A. Giordano of "The Search for the *Culloden*," December 1976) found the ship's remains and conducted an underwater archeological dig on the site. Last year Moeller's efforts were rewarded in a small way when the ship was named to the National Register of Historic Places. Being on the register affords some protection to the site, since it marks it as a cultural resource that must be taken into account if a government project affects it.

Unfortunately, it affords no protection against the colonists, who are still snatching what they can from the more than 500 wrecks that went down off Montauk in the last 200 years. The difference is that now they have scuba gear. The *Culloden* site has little left to take, but Moeller suffered problems from pilferage while he was waiting for official approval to conduct the dig. And many other wrecks with artifacts of historic value are regularly picked over by divers, according to Moeller, who sees little hope for a change in the situation. There are laws on the books to protect the wrecks, but no real provision for enforcement.

*James Gorman*

# 1980 RABBIT DIESEL
# NEW YORK TO WASHINGTON ON ONLY 10 GALLONS

No, we're not kidding. You could actually zip from Lincoln Center all the way to the Lincoln Memorial and back (about 466 miles), on just 10 gallons with a Rabbit Diesel.

## AND BACK!

Rabbit Diesels are the top two mileage cars in the country. In fact, the 5-speed version gets an EPA estimated $\boxed{42}$ mpg, 56 estimated highway. The 4-speed gets an enviable $\boxed{40}$ estimated mpg, 52 estimated highway.

(Use "estimated miles per gallon" for comparisons. Your actual mileage may vary with speed, weather and trip length. Highway mileage will probably be less.)

And don't forget, a Rabbit comes with traditional Volkswagen craftsmanship, front-wheel drive, loads of room for people and things, and also happens to be the least expensive Diesel you'll find anywhere.

All that, plus the #1 mileage record in the country.

Add it up, and not only is the Diesel the choicest candidate of the year, the Rabbit is the choicest Diesel.

So the next time you're considering trading Fifth Avenue for Pennsylvania Avenue, consider doing it in a 1980 Rabbit Diesel.

It'll get you something no other car available in the country can get you on only 10 gallons.

Home.

## VOLKSWAGEN DOES IT AGAIN

© 1979 VOLKSWAGEN OF AMERICA

# We won it one island at a time

Guadalcanal...Tarawa...Peleliu—places nobody had ever heard of until they became bloody steppingstones on the road to Japan. *Island Fighting* recaptures it all as your introduction to the WORLD WAR II series by the Editors of TIME-LIFE BOOKS.

**Examine it with no obligation to buy.**

You'll see front line photographs of the assault on Betio...jungle warfare in Papua...carrier action...the unique bag of tricks used by the U.S. Fifth Air Force, from parafrags to skip bombs...the lonely heroism of the coastwatchers far behind enemy lines.

Fast-paced yet authoritatively detailed, *Island Fighting* takes you into high military councils and planning sessions. You'll read about MacArthur's strategy battle with the Navy and watch Japan shift from offense to defense as the fortunes of war changed with the fall of Saipan.

**The complete story of the War.**

Whether you fought in World War II, lived through it or simply want to know more about it, this is the account you'll want to read. The action unfolds volume by volume from the first Axis attacks and our harrowing early days of confusion and defeat to the final days of victory. The complete story told as only TIME-LIFE BOOKS could tell it.

# So Firm a Friendship

*Some guarding dogs follow, and defend, a flock of sheep as if they were part of it*

**by Lorna Coppinger and Raymond Coppinger**

In the *Voyage of the Beagle*, Charles Darwin wrote, "When riding, it is a common thing to meet a large flock of sheep guarded by one or two dogs, at the distance of some miles from any house or man. I often wondered how so firm a friendship had been established."

In the spring of 1977, we began our own attempt to investigate the basis of this friendship, traveling from Hampshire College in the hills of western Massachusetts to the sheep pastures of Europe, in search of a "new" biological solution to an old biological problem: predation on sheep by wolves, dogs, and other canids. High in the newly green mountains of Macedonia in southwestern Yugoslavia, we established contact with several shaggy descendants of this region's legendary sheep-guarding dogs. For days we had watched thousands upon thousands of long-tailed, white-faced woolly sheep being moved by shepherds from the lowlands, through large culverts under highways, up the eroded trails of the foothills to their summer range in the Šar Planina. Plodding along shoulder to shoulder with the sheep, shepherds, and pack ponies were the dogs: two or three sheep-sized dogs for every half mile of sheep.

To test for ourselves the dogs' reputation we approached a flock of several hundred sheep, watching the placid dogs out of the corners of our eyes. Our approach roused a dog from his afternoon reverie, and he moved slowly so that our path to the sheep now included him. He seemed unconcerned and relaxed, but when we got to about fifty yards from the nearest sheep, we decided that we had reached our safe limit. The dog still showed no overt threat, but a slight change in his stance and the lowering of his head and tail as he watched us convinced us of his guarding abilities.

In later months we would watch similar behavior in dozens of Old World sheep-guarding dogs: Italian maremma, Yugoslavian šar planinetz, Turkish (Anatolian) shepherd, Hungarian komondor and kuvasz, and also two Russian-type ovcharkas (sheepdogs) that our colleague Susan Goldhor brought to Hampshire College from the mountains of Turkey near the Russian border. In all the dogs, we noted what Charles Darwin wrote in 1833 about the sheep-guarding dog in South America: "It has no wish to leave the flock, and just as another dog will defend its master, man, so will these the sheep. It is amusing to observe, when approaching a flock, how the dog immediately advances barking, and the sheep all close in his rear, as if round the oldest ram."

The year before, we had been discussing traditional European guarding dogs with Richard Wheeler and Hudson Glimp at the Winrock International Livestock Research and Training Center in Arkansas. As leaders in the sheep industry, they were well aware in 1976

*From Portugal to Tibet, sheep-guarding dogs, such as these Hungarian komondor, are the pride of shepherds. U.S. sheepmen, plagued by coyotes and marauding dogs, are now looking to this Old World means of predator control.*

STEREO/FM-AM RECEIVER STR-V55

# THE COMPANY THAT VIRTUALLY INVENTED TRANSISTORIZED HIGH FIDELITY HAS JUST REINVENTED THE RECEIVER.

For three decades the engineers at Sony have een behind not just one or two, but eighteen major chnological innovations in high fidelity. One of our ngineers even won a Nobel Prize.

The fact is, much of the hi-fi equipment made day is based on technology developed at the audio bs of Sony.

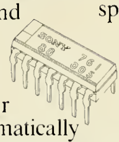
And now Sony introduces the new STR-V55. The ceiver that, we assure you, will send the competition eling back to their drawing boards. Especially when ey note its list price.

A COMPUTER FINDS YOUR STATION.

Unlike our competitors, we didn't just make a few nprovements in an ordinary receiver and call it "new."

We actually reinvented it.

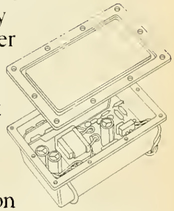
Instead of using the same basic tuning mechaism that's been found in radios since the days of larconi, the new V55 uses microprocessor tuning to isure crisp, clear, perfect sound. We call this "quartz equency synthesized tuning." It's totally computerized. o there are no strings, pulleys, flywheels, or other echanical paraphernalia that can wear out and ecome less accurate as the years go by.



Equally innovative is a memory feature at lets you preselect up to eight AM or FM ations for instant push-button tuning. Use our xclusive "memory scan" device and you automatically ear 3.5 seconds of each. And there's a three-position uting level switch that enables you to hear only the ations you want to hear—and never the noise in etween.

PULSE POWER: ANOTHER SONY FIRST.

Even the most sophisticated ear would have quite difficult time hearing any distortion in the new ony V55 receiver. That's because, statistically, the V55 uts out 55 watts per channel from 20 to 20,000 hertz with less than 0.02% total harmonic distortion.



One of the reasons: an incredibly advanced, Sony developed "Pulse Power Supply." It not only completely eliminates any trace of audible distortion, but it's a fraction of the size and weight of conventional power supplies. So it doesn't require a forklift truck to carry it home from the store.

All this adds up to the elimination of hum and noise and, when combined with the V55's DC power configuration, delivers richer, cleaner bass response.

ADVANCEMENTS, MORE ADVANCEMENTS AND STILL MORE ADVANCEMENTS.

Naturally, we could go on and on about such things as the V55's new transistor design which greatly extends the high-frequency range for more accurate sound reproduction.

Or about our switches that allow you to record automatically from one tape deck to another—without spending half your time rearranging wires.

Or about our special low filter device that lets you remove subsonic noise from your records without removing music.

Or about how the V55 is the one state-of-the-art receiver that won't require you to get a second mortgage to purchase it. And we at Sony confidently state it's by far the best investment you can make in hi-fi this year.

For more information on the complete line of new Sony receivers and the name of your nearest Sony dealer write: Sony, P.O. Box CN-04050, Trenton, New Jersey 08650.

**SONY AUDIO**

It's all you need to know about high fidelity.

:ATURES AND SPECIFICATIONS: 55 watts per channel with 0.02% distortion/Quartz freq. synthesis AM-FM/8 station memory IC (nonvolatile)/4 way tuning system/3 position tuning level/Pulse wer Supply/Hi-$f_T$ output transistors/M/C cartridge capability/Dual tape monitoring and dubbing controls/Subsonic Filter (15 Hz-12 dB per oct)/Gold-plated phono input.

NOVA PACIFICA PUBLISHING COMPANY LTD.
P.O. Box 11106, Wellington, New Zealand.

of the need of United States sheep producers for more help in protecting their flocks from predators. Since 1972, when the poison known as compound 1080 was banned on public grazing lands, the coyote problem had increased steadily across the western United States, and so had the cost of predator control. Despite the $30 million spent in one year on control of canids, well over a million sheep were reported lost, mostly to coyotes.

Government statistics on losses to coyotes in the major western sheep-producing states vary from 8 percent of all lambs born to 2 percent of the annual sheep inventory. Percentages do not, of course, reflect individual experience. Sheep farmers on the periphery of a sheep-raising area frequently serve as a buffer for those in a more protected situation, and since their ranges are more exposed to predators, they may suffer heavier losses.

And, of course, what a loss means to a shepherd is another thing. One Massachusetts shepherd lost twenty-five of his forty-four ewes in one night, killed by dogs in his barn. His lambs, in another section, survived, but then he had to absorb the cost of bottle feeding thirty-four two- to five-week-old lambs. A Boston businessman who raises cattle on thousands of acres in Arizona told us that no loss is "acceptable," and that an 8 percent yearly toll would put him out of the livestock business.

Modern research has produced sophisticated methods of predator control, including such lethal and nonlethal devices as toxic sheep collars, cyanide guns, repellent odors, traps with tranquilizers, chemosterilants, and supercharged electric fences imported from New Zealand. Applying these systems is fraught with frustrations: scientists at Colorado State University concluded that no chemical odor they had found would consistently repel canids without also adversely affecting sheep; researchers at the Denver Wildlife Center noted that commercially available tranquilizers were prohibitively expensive for large-scale use; at Texas A & M University, investigators found that the resourceful coyote, while preferring to go under or through fences, rose to the challenge of five-foot barriers and promptly learned to jump them.

Besides these technical snags, there is a controversy over what predator control methods are acceptable. A November 1979 directive from Secretary

# Fill out this check (or use your own) and save the children

For only 52¢ a day (just $16 a month) you can befriend a needy child through Save the Children. Your money, combined with that of other sponsors, can breathe new life into an impoverished village…help hardworking people in their fight for dignity…turn despair into hope for a child who has known only disaster. 52¢ may not buy much where you live. But for the poorest of the poor, where the need is so desperate, it can work miracles.

For your first monthly sponsorship contribution, just fill out and sign the check at the top of this page (yes, as long as you indicate your bank name and account number, it is negotiable). Mail the entire page to Save the Children. Of course, you may use your personal check if you prefer.

## TELL US HOW YOU WANT TO HELP BY ANSWERING THESE QUESTIONS.

Your name ______ (please print)

Address ______

City ______ State ______ Zip ______

**1 What kind of child would you like to help?**
☐ Boy ☐ Girl ☐ Either

**2 What geographical area are you interested in?**
Urgent need exists in all the areas listed below. Select an area, or let us assign a child where the need is greatest.

- ☐ **Where the need is greatest**
- ☐ Africa
- ☐ Bangladesh
- ☐ Chicano (U.S.)
- ☐ Colombia
- ☐ Dominican Republic
- ☐ Honduras
- ☐ Indian (U.S.)
- ☐ Indonesia
- ☐ Inner Cities (U.S.)
- ☐ Israel
- ☐ Korea
- ☐ Lebanon
- ☐ Mediterranean
- ☐ Mexico
- ☐ Southern States (U.S.)
- ☐ Sri Lanka (Ceylon)

**3 Would you like a picture of your sponsored child?**
Shortly after we select a child for you, we can send you a photograph and brief personal history, if you desire.
☐ Yes ☐ No

**4 Would you like to correspond with your sponsored child?**
If desired, correspondence can help build a meaningful one-to-one relationship. Translations, where necessary, are supplied by Save the Children.
☐ Yes ☐ No

**5 Would you like information about the child's community?**
Several times a year you can receive detailed reports on community activities to benefit your sponsored child. These community reports show how your money is being used most effectively for permanent improvements to the child's environment—for health care, education, food production, nutrition, and community training. Would you like to receive such information?
☐ Yes ☐ No

**6 Do you wish verification of Save the Children credentials?**
Save the Children is indeed proud of the handling of its funds. Based on last year's audit, an exceptionally large percentage (80.3%) of each dollar spent was used for program services and direct aid to children and their communities. Due to volunteered labor and materials, your donation provides your sponsored child with benefits worth many times your total gift. Would you like to receive an informative Annual Report (including a summary financial statement)?
☐ Yes ☐ No
*(A complete audit statement is available upon request.)*

**7 Would you rather make a contribution than become a sponsor at this time?**
☐ Yes, enclosed is my contribution of $______.
☐ Check here for general information about our unique programs for aiding impoverished children.

Ceramic Radiant Heat
2903 Pleasant Dr., Lochmere, N.H. 03252 (603) 524-9663

of the Interior Cecil D. Andrus stated that official policy for federal grazing lands would now emphasize nonlethal, noncapture methods of control, that only the animals actually doing the damage would be removed, and then only by humane methods. Thus the conflict between the global need for food and fiber and the ethical question of attacking a wild species is intensifying. On hearing the news from Secretary Andrus, large-scale producers began thinking seriously about livestock-guarding dogs.

Only two breeds of traditional European guarding dogs were known to a handful of U.S. farmers by the mid-1970s. Although both the French/Spanish great pyrenees and the Hungarian komondor and kuvasz had been available commercially for several decades, the kuvasz was not used with livestock, and the success of the others as sheep guardians in the United States was highly variable. Some dogs reduced predation while others added to it. Farmers were naturally reluctant to trust their sheep to unsupervised dogs.

In Europe and Asia, however, using dogs to control predators has a long history. For shepherds to have so many big dogs, they all must earn their keep. The Spanish shepherds who brought sheep to the New World thought enough of their guarding dogs to bring them, too. Today, from Portugal to Tibet, the various guarding breeds are the prides of the shepherds and are kept by many. Although wolf and lynx populations are greatly reduced in most of Europe and southwestern Asia, they, along with human thieves, still pose a problem to shepherds. In fact, the night before we confronted our first šar planinetz in the mountains of Yugoslavia, a wolf had bothered the flock.

At Hampshire College, our initial two years of research included importing ten pups of three different breeds from European working stock, breeding and raising the first U.S. generations, noting behavior, and then placing seventy young dogs out on farms and ranches across the country. Our experience has mirrored much of what Darwin recorded.

Darwin was one of many observers who assumed that the guarding behaviors must reflect careful training:

> The method of education consists in separating the puppy, while very young, from the bitch, and in accustoming it to its future companions. An ewe is held three or four times a day for the little thing to suck, and a nest of wool is made for it in the sheep-pen; at no time is it allowed to associate with other dogs, or with the children of the family.

We found out, however, that the behavior of the guarding dogs is primarily unlearned. There is little one needs to do with these dogs to foster three characteristic, and necessary, behaviors: nonaggression toward the sheep, attentiveness to the sheep ("following instinct"), and defense of the sheep. These behaviors contrast dramatically with those of herding dogs such as border collies, which have been bred to capitalize on their basic instinct to stalk and chase. With herding dogs, the shepherd regulates the rate and direction of the chase and inhibits its predatory outcome. Depending on how intense this instinct is, farmers can select more timid breeds or strains for work with smaller livestock, such as sheep, and more aggressive dogs for cattle.

If puppies of both guarding and herding breeds are raised together, one finds little difference in their behavior until puberty (about seven months old). Play behavior and social development occur at similar rates, with the guarding dogs tending to be more dominant, apparently for reasons of size. Of course, a small guarding dog bitch may be dominated at the food pan by a larger male herding dog.

Nearing puberty, the border collie herding dogs we worked with suddenly developed a new behavior called "eye," in which the dog stares fixedly at an object. It is basically a stalking behavior. The frequency of this behavior was extraordinary, sometimes absorbing the dogs during most of their active periods. Eye became a permanent part of the dogs' play repertoires and at times groups of border collies would eye each other or some other object (such as an apprehensive chicken) for hours. One female would kick up dust, leap around, and eye its descent, over and over. Motion or the anticipation of motion seemed to be an important stimulus for eliciting this eye behavior. Closely related, and also age-dependent, are the behaviors of other working breeds of dogs, such as pointing in pointers and setters or retrieving in retrievers.

The guarding dogs, on the other hand, show no new motor patterns at puberty. Instead, the dogs' juvenile behavior is retained and its strength intensifies. They play and fight harder and,

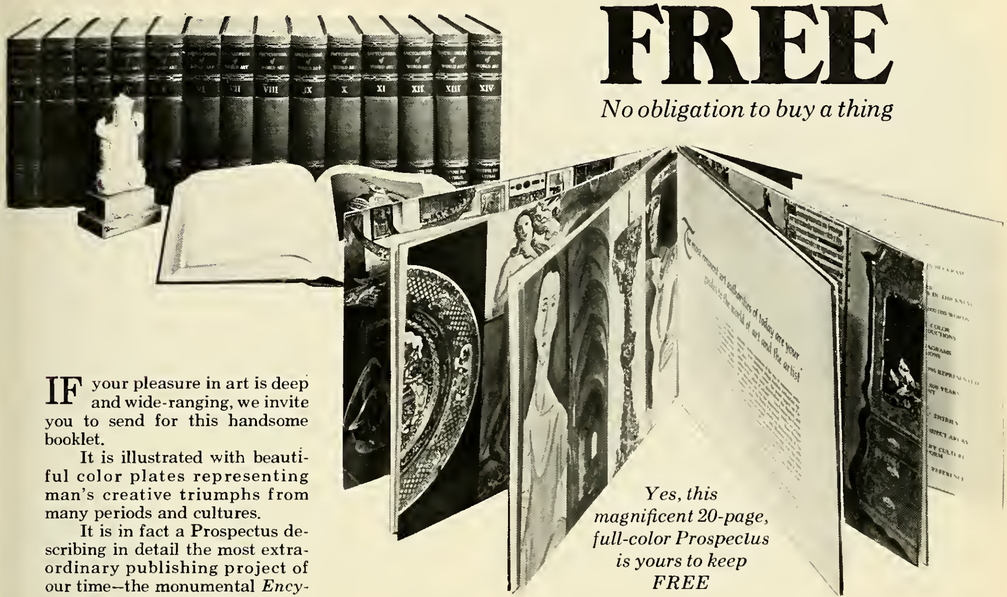
# 20,000 years of Great Art FREE

*No obligation to buy a thing*



*Yes, this magnificent 20-page, full-color Prospectus is yours to keep FREE*

IF your pleasure in art is deep and wide-ranging, we invite you to send for this handsome booklet.

It is illustrated with beautiful color plates representing man's creative triumphs from many periods and cultures.

It is in fact a Prospectus describing in detail the most extraordinary publishing project of our time—the monumental *Encyclopedia of World Art* in 15 volumes.

The Prospectus is free. We hope the sampling will arouse the same excitement in you that the Encyclopedia has aroused in the entire art world. But you incur no obligation in requesting a copy. No salesman will call.

**20,000 years of Great Art:**
**Over 16,000 illustrations, 2,000 in full-color**

*The Encyclopedia of World Art* embraces man's greatest achievements in the visual arts through 200 centuries of productivity. To turn the pages of these prodigious volumes . . . to read, to learn, to explore their visual delights . . . is a remarkable experience.

There are hundreds of absorbing factual articles, prepared by the most eminent art authorities. In more than 7,000 superb full-page plates—measuring a full 9 inches by 12 inches in size—you will view rare treasures of renowned museums and private collections all over the world. Not only paintings, sculpture and architecture—but every art from armor to textiles, ceramics to tapestry, fashions, furniture and landscape gardening, ivory, jade and stained glass, jewelry and silver. More than 16,000 works of art are shown, almost 2,000 of them in magnificent color.

A convenient Reader's Guide shows you how related articles can enrich your understanding of any art subject you wish to pursue.

With your free color Prospectus, you will learn how you may examine Volume I at leisure in your home and, if you wish, become a subscriber to the Encyclopedia on a convenient budget plan. So, send today for your FREE Prospectus. There is no obligation and nobody will visit or phone you.

## Encyclopedia of World Art

*Mail card for your free Prospectus*

*Or, if reply card has been removed write:*
McGraw-Hill Book Dept. AY-148
1221 Avenue of the Americas, New York, New York 10020

*Commended by the world's foremost art critics:*

"An essential possession for anyone with a serious personal or professional interest in art . . . a work to be explored, studied and enjoyed." Harry Einbinder, *The Saturday Review*

"A great landmark in art publications—a monumental undertaking." Dorothy Adlow, *Christian Science Monitor*

"Packed with wonders." John Canaday, *New York Times*

"One of the most spectacular—and praiseworthy—achievements in the field of literature and fine arts."
Rex Barley, *Los Angeles Mirror News*

The Amazing Stirling Cycle **Hot Air Engine**

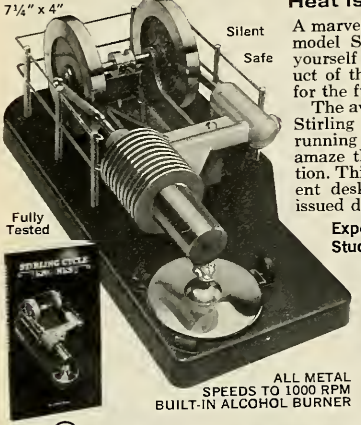
**Heat is the only fuel required!**

7¼" x 4"

Silent

Safe

Fully Tested



A marvelous opportunity to acquire an early model Stirling Cycle Engine and acquaint yourself with little known facts about a product of the past that may well hold promise for the future.

The average person has never heard of the Stirling engine, so the sight of one quietly running with heat as its only fuel will at first amaze them and then excite their imagination. This is the first in a family of six different desk-top model hot air engines to be issued during the next three years.

**Experimenters • Hobbyists' Power Source**
**Students • Collectors • Model Engineers**

An easily read, lavishly illustrated, 128-page book accompanies each engine or may be purchased separately. This publication, the first of its kind, takes the reader on a 160-year tour through the world of Stirling Cycle Engines. Illustrations include the Stirling, Roper, Heinrici and the amazing new Stirling-powered Ford Torino!

NH 0380

as Darwin noted, this can be a real problem for sheep: "Their most troublesome fault, when young, is their desire of playing with the sheep; for in their sport they sometimes gallop their poor subjects most unmercifully." Often an aggressive ram or ewe curbs this overplayful behavior with a foot-stamp or butt, or the shepherd intercedes by punishing or restraining the dog for a while.

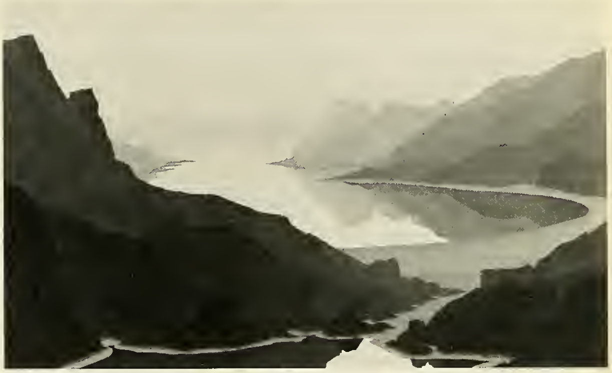
Once past this juvenile stage, however, the dogs and sheep form a social bond. An adolescent dog's sexual behavior often becomes part of the play. A dog will solicit play from a sheep with a play bow, followed by a chase if the sheep will run. The sheep is at a disadvantage in this play, often losing wool or worse. If the sheep stands, the dog may mount the animal and include pelvic thrusts, often protracted if the sheep seems receptive. Another sexual pattern exhibited by the dog is to nuzzle the sheep's ear, sometimes hanging on to it if the sheep tries to move away. The result can be a torn ear.

If the sheep demonstrates aggression toward the dog's play bow by lowering its head and walking slowly and steadily toward the dog, the dog may retreat, showing characteristic submissive behavior by lowering its haunches and turning a back knee out. Frequently, a guarding dog will start licking a sheep's face in a routine reminiscent of a food-begging performance used by pups to get their mother to regurgitate food. Sheep will often tolerate this licking for long periods.

After the dog matures, the rambunctious play decreases in intensity, although many of these behaviors remain long into its adult life. Two-year-old dogs, more stately in motion, will walk up to a flock, lick a face, nuzzle an ear, act submissive, or mount a sheep. Experienced sheep pay little attention or participate moderately.

The behaviors that spell success for a guardian are absence of the stalking, chasing instinct and a curious mixture of juvenile, maternal, and courtship behavior directed toward the sheep. We often hear a shepherd say that the dog thinks he is a sheep. More likely the dog is treating the sheep as if they were other dogs. Dogs dominate sheep, drive them from food with a characteristic vocal warning, nuzzle their ears, and lick their genitals; even try to copulate with them. Some dogs and bitches will lick newborn lambs clean and cuddle them in the crotch of

# How to tell original prints from cheap reproductions.



Jerome Schurr's *Padres Bay*, original serigraph. Signed limited edition of 290.

Buying original prints is an excellent way for the novice to make a modest investment in beautiful works of art.

The buyer had better beware, however.

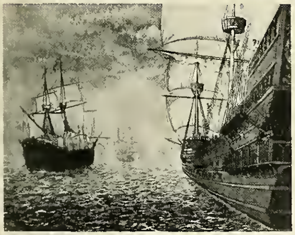
As more and more attention is being given to art as an investment, more and more dealers are trying to pass off cheap reproductions as fine art.

At the Original Print Collectors Group, we sell only fine original works to a growing number of people who are enthusiastic about buying good art at moderate prices.

One of our primary concerns is to educate our customers, so that they'll be able to discriminate and get true value for their money. A few pointers, then about original prints:

Original prints, whatever the process used to create them, are "hand-pulled" under the artist's supervision, or by the artist himself. This means that any work produced photographically or by another purely mechanical process is not an *original* print.

If you examine a print under a magnifying glass and discover a regular pattern of small dots, you will know immediately that it is not an original work.



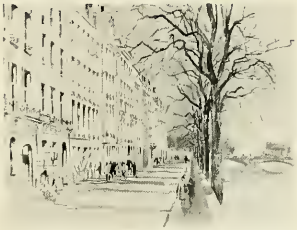
Paul Tappenden's *Voyage to the New World*, original etching. Signed limited edition of 250.

If the print is a serigraph (produced by a silkscreen process), the ink will seem rather like paint and appear to be sitting upon (rather than absorbed into) the paper.

Etchings and engravings will produce a physical impression on the paper itself.

Contemporary original prints will always be signed in pencil by the artist himself, to indicate personal supervision and approval of the individual print.

Original prints are always produced in limited editions, at the most several hundred copies. If thousands of copies are available, then the work is almost certainly *not* original. (In most cases, to assure that the integrity of their work is not violated, artists will destroy the plate after the edition has been produced.)



Pierre Pages' *Quai d'Orleons*, original lithograph. Signed limited edition of 225.

The print will have a figure on its border, indicating the number of prints pulled and the number of the individual print in the sequence.

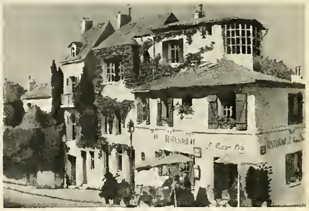
For example, the figure 50/100 means that the edition has been limited to 100, and that this is the 50th print pulled.

## Is the edition limited and is the print numbered? Did the artist personally sign the individual work?

There's a lot more to be learned about buying original prints, more than we can tell you on this page.

But if you'll send for our free color catalog, we'll be happy to tell you more, and show you the quality and variety of the prints we offer.

They include limited edition etchings, serigraphs and lithographs by both contemporary and traditional artists with international reputations. Some examples: Calder, Chagall, Dali, Miró, Vasarely, Picasso and Renoir.



Denis Paul Noyer's *Maison Rose*, original lithograph. Signed limited edition of 295.

If you decide to buy a print, we'll frame it handsomely and send it to you with a full money back guarantee. If you're not satisfied for any reason, you simply return your print and get a full refund.

We'll also send you a catalog, every two months, featuring new selections of prints, along with an informative newsletter.

If you're interested in investing in art, invest a 15¢ stamp in your art education and send for our catalog, today.

Smaller can be better, as the new full-power Nikon Roof Prism Compact Binoculars clearly demonstrate. Pocket-size slim and just 7-1/2 ounces light, they outperform many bigger and heavier binoculars in sharp, bright, distortion-free viewing. You see the entire scene, even while wearing glasses. And, most important, they're so precisely engineered that you can view for extended periods, without strain or discomfort. Available in all-purpose 6x, 7x and 8x models. See the difference Nikon quality makes, at Nikon camera dealers and selected optical departments. Or write to Nikon Inc., Dept. N-26, Garden City, New York 11530. their hind leg, curling around them as if the lamb were a puppy.

All these behaviors lessen the chances that a dog will kill a sheep and also predispose the dog to follow the sheep. The behaviors closely resemble those that one might record among members of a pack of wolves. The dog is treating the sheep like other dogs; the sheep are treating the dogs like other sheep. Both sheep and dogs, together in a flock, respond to each other's feeding behavior and alarm signals, and they sexually solicit one another.

In studying this social bonding, we have tried to manipulate its development. Cynthia Arons, a fourth-year student at Hampshire College, divided six litters of guarding and herding dog pups shortly after birth and suckled half on sheep and half with their own mothers. She was looking for confirmation of the presumed benefit derived from the traditional technique of suckling pups on ewes, as reported to us—as well as to Darwin—by numerous shepherds. The dogs, now in their second year, show no difference in social attachments to sheep. In fact, some Anatolian shepherd dogs, which were donated to the project at an age of six months and had never seen a sheep before, seemed delighted with their new friends in our sheep pasture and went right to work. We still advise farmers, however, to raise their dogs under close observation, particularly until they are at least a year old.

How then do the sheep gain protection from predators by the presence of guarding dogs? First and most important is that most predators will not risk approaching a flock where one or more 100-pound dogs are on duty. Sheep predators are mainly canids, and most of the primary social signals are common to wolves, coyotes, and dogs. Much of the time we cannot tell directly how effective the guardians are because when they are with the sheep, nothing happens. Predation is usually erratic, so the lack of it is hard to measure, especially since it may be simply the dog's presence or barking that warns the predator away. Nevertheless, we have recorded some clear instances of steady predation that stopped, literally overnight, when adult dogs were put out with the flock.

The second protective mechanism is closely related to the first. Dogs are attracted to other dogs. A potential predator may enter a field with mutton on his mind but he can be quickly diverted into sniffing rear ends and pos-

# It is time to introduce a new generation to THIS MASTERWORKS COLLECTION

## Accept this magnificent volume from the publishers as an outright gift.

Masterpieces of the bookbinder's art, richly decorated, with gilded page top ends, ribbon marker and other luxury touches.

More than three generations ago, Doctor harles W. Eliot, the revered President of irvard University, made his now-famous ection of the most powerful, most influtial works of mankind through the ages: IE HARVARD CLASSICS.

He singled out ideas that changed history. ›vels with a timeless power to entertain. ıys. Amusing and, at the same time, ›ught-provoking essays. Books that nain as readable today as the day they re written, because, unlike so many longgotten "best sellers," they speak to unirsal emotions and knowledge.

We are pleased to be able once more to 'er THE HARVARD CLASSICS to a w generation in The Collector's Edition.

**gift to establish a family tradition**

fore you consider any purchase whatso-:r, you can own and explore the volume . Eliot called "the crown of the world's ımatic literature." In its beautifully nted and bound pages you'll relive Marlowe's drama of royal self-destruction, *Edward II;* you'll thrill to Shakespeare's genius in *Hamlet, Macbeth* and *King Lear;* and you'll enjoy the magic of *The Tempest.*

This truly magnificent volume is yours free as an introduction and a sampling of the reading ahead.

If you like, you can go on to build a library of your own choosing with The Collector's Edition. You can share its towering works with your family and give them a wealth of reading you can all return to again and again over the years.

The Collector's Edition contains 25 volumes. 1228 incomparable works from 287 of the most astonishing minds of the past 2,000 years—from the wisdom of Plato to the rollicking wit of Mark Twain. Poetry. Tales of adventure such as *Two Years before the Mast* and *Don Quixote.* Even beloved fables by Hans Christian Andersen.

If you enjoy owning books that look and feel the way *all* books once did, you'll be delighted when you receive your free volume.

## The Collector's Edition THE HARVARD CLASSICS

**FREE BOOK CERTIFICATE**

The Harvard Classics Dept. JC
*Grolier Enterprises Corp.*
Sherman Turnpike
Danbury, Conn. 06816

Mail this certificate today and get Volume 1 of the 25-volume Collector's Edition of THE HARVARD CLASSICS with no obligation to buy anything.

If you're not delighted with your free book, write "cancel" on the slip that comes with it and mail the slip back to us. You will receive no further books—and Volume 1 is yours to keep—FREE.

But if you want to continue, do nothing. You'll get a second book—on approval—six weeks after your free book. If you keep it, pay just $9.95 plus shipping and handling.

Then, six weeks later, you'll receive a third volume and six weeks after that if you haven't canceled you'll receive the other twenty-two books in one shipment to complete your Collector's Edition of THE HARVARD CLASSICS. Note: You pay for only one book a month...that's $9.95 plus shipping and handling per book.

Remember, you get every book on approval. You can cancel at any time. You can buy as many or as few as you wish—even none at all. The magnificent first volume is yours to keep absolutely free, no matter what you decide. As a subscriber you will also be entitled to receive, for FREE examination, any annuals that are published. You may purchase only those you wish to own.

turing with the guarding dog. If the new animal establishes dominance over the guardian then it might go on to kill sheep, but more times than not, size wins out and the shepherd finds a submissive neighborhood pet, unharmed, in the field.

Third, our guarding dogs respond negatively to any new stimuli, any small changes in the routine activities of a pasture. Barking is elicited by minor stimuli; habituation to these is slow. The guardians' apprehension is heightened in the twilight periods of the day, when coyotes and unwanted dogs are most active. Guardians react to potential encroachers with barking, usually with their tail down and ears back. This is typical "fight or flight" behavior. In young dogs the tendency is to flight, but the more mature will stand their ground, although they seldom move far from their "supporting" group of sheep. This means the dog stays with the flock, approaching an intruder and then retreating, its courage waxing and waning according to its proximity to the sheep. If there are two or more guardians present, they will form an alliance, which puts a serious predator at a disadvantage.

Preliminary reports on the first trials of our guarding dogs are encouraging. The nearly seventy farmers and ranchers who have been cooperating with the Livestock Dog Project report that during their first two years most of the dogs have shown the social attachment to sheep that is necessary for effective guarding. The rest of the dogs may need another year to develop reliability. Some may never make it.

How many sheep have been saved these first two years? We have no hard data yet, but most of those using the dogs write that since the guardian joined their sheep, very few predators have ever been seen. One farmer did lose eight sheep to two local pet dogs while his two young guardians stayed bunched with the flock. These littermates have since been separated and sent to other farms, and maturity seems to be increasing their confidence. Another farmer with three sheep pastures and two dogs lost sheep one night but only in the one unguarded pasture. A third farmer who had been losing a lamb a night lost no more once an experienced guarding dog joined his flock.

Darwin wrote,

> A whole pack of the hungry wild dogs will scarcely ever (and I was told by some never) venture to attack a flock guarded by even one of these faithful shepherds. The whole account appears to me a curious instance of the pliability of the affections in the dog; . . . We can understand on no principle the wild dogs being driven away by the single one with its flock, except that they consider . . . that the one thus associated gains power, as if in company with its own kind.

The bond formed between the two species, dogs and sheep, results in a firm friendship indeed. From both historical and biological points of view, guarding dogs hold the promise of an environmentally sound, cheap way of reducing predation on livestock.

*Lorna Coppinger, a faculty associate in biology, and her husband, Raymond Coppinger, a professor of biology at Hampshire College in Amherst, Massachusetts, run the Livestock Dog Project at Hampshire's New England Farm Center. They have been studying the behavior and physiology of dogs since the early 1960s.*

*Sheep raisers say that dogs such as these Turkish shepherds think they are sheep. More likely, the dogs treat the sheep as if they were other dogs: nuzzling their ears, licking their genitals, even trying to copulate with them.*

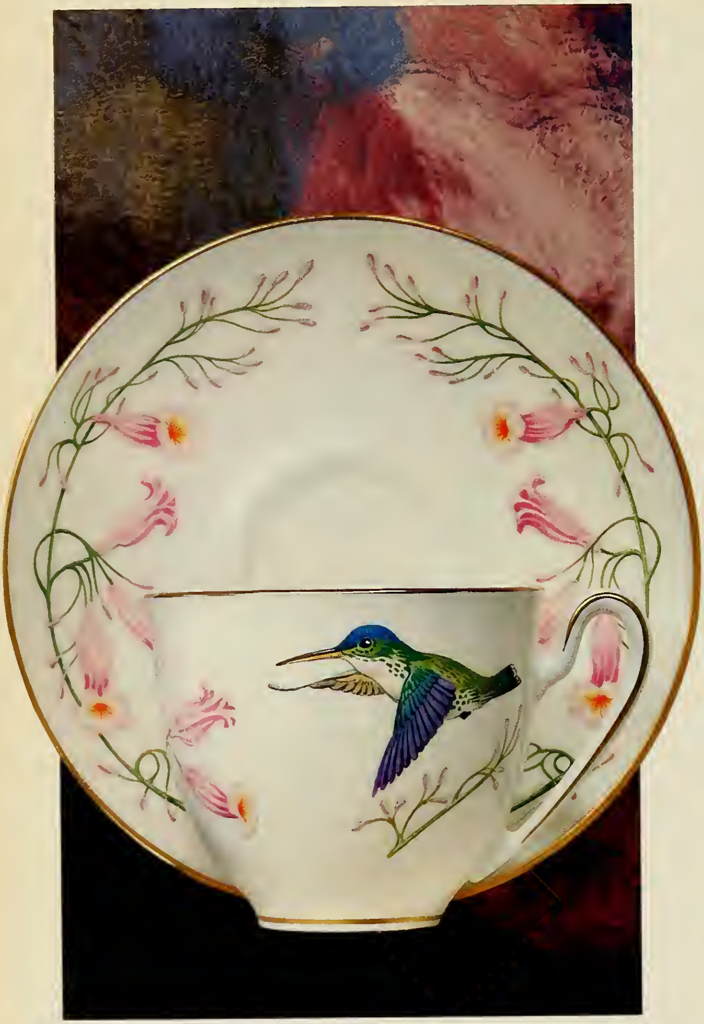
The World Wildlife Fund announces
a most important new porcelain collection



# hummingbirds of the world

by Robin Hill

The shimmering, iridescent beauty of hummingbirds—
captured in an enchanting collection of twelve cups and saucers
by one of the world's most distinguished bird artists...
his first works of art in porcelain.

*Each cup and saucer will bear*
*a new work of art created by Robin Hill*
*exclusively for this limited edition.*
*And each will be decorated*
*with pure 24 karat gold.*

**The Artist.** Robin Hill is recognized as one of the world's finest bird portraitists. His paintings of birds have been exhibited in leading art galleries throughout the world—including a spectacular show at the famed Corcoran Gallery of Art in Washington, D.C. He is represented in many important public and private collections, including the Dublin Museum of Art and the collection of HRH Prince Philip, Duke of Edinburgh. And plans are being made for a museum to house his work exclusively—an honor accorded to few artists throughout history.

Hummingbirds—"winged jewels" they have been called—demanded a very special medium, because of their brilliant gem-like coloration and tiny size. And so Robin Hill created a unique and extraordinary series of works of art for *cups and saucers* of fine porcelain, in a tradition that dates back more than two centuries.

Thus, at the height of his career, Robin Hill has now created *his first works of art in fine porcelain*. An extraordinary series of twelve collector's cups and saucers of fine porcelain, portraying the glossy brilliance and shimmering grace of hummingbirds—in authentic detail—with all his incomparable artistry.

Each of these twelve collector's cups and saucers is a separate, unique, and wonderful work of art created exclusively for this limited edition. Together, they form an extraordinary collection that will be a treasured acquisition for everyone who loves the beauty of birds, of art and of fine porcelain.

**The Hummingbird cups and saucers.** The collection is an official issue of the World Wildlife Fund, the world's largest privately supported nature conservation organization. It is the World Wildlife Fund's *first* international issue in porcelain.

The cups and saucers will be crafted in fine Bavarian porcelain, whose exceptional whiteness is ideally suited to bring out the dazzling beauty of the hummingbirds. And each hummingbird will be associated, in Hill's superb works of art, with its favored flower. The vivid leaves and bright blossoms provide a perfect setting for the hummingbirds shown on the front and back of each cup.

Here is how the great naturalist painter John James Audubon described this beautiful, tiny bird:

> "A glittering fragment of the rainbow...
> moving through the air...as if by magic...
> yielding new delights wherever seen."

Robin Hill's meticulously accurate works of art—at once brilliant and subtle, striking and completely natural—capture these miracles of nature in all their beauty, in as many as 16 separate ceramic colors. And each cup and saucer is bordered by bands of pure 24 karat gold, hand-applied to complete the design. The result is a collector's joy...true limited edition works of art in porcelain that will form a focal point of beauty wherever you display them.

**The limits of edition.** The World Wildlife Collection of Hummingbirds of the World Cups and Saucers will be produced only once, and in strictly limited edition, with an absolute closing date of March 31, 1980.

The cups and saucers will be crafted solely for subscribers. Individual cups and saucers will not be sold separately. And there is a further limit of one subscription per collector.

The total edition will thus be forever limited to the exact number of original subscriptions entered by March 31, 1980.

**Subscription deadline: March 31, 1980.** The collection will be issued on a convenient subscription plan, at the rate of one cup and saucer every other month. The original issue price of just $39 per cup and saucer is payable in two equal monthly installments of $19.50 each. And each cup and saucer will be accompanied by a special stand, so that you can display them in your own home just as they are shown on these pages—the saucer on its edge and the cup in front of it, forming a charming and complete composition.

In addition, each cup and saucer will be accompanied by a commentary written especially for this collection, describing the hummingbird portrayed, its native habitat, its favored flowers and much other fascinating lore. A Certificate of Authenticity, attesting to the limits of edition, will accompany each collection.

There is no need to send any payment with your application. But your Subscription Application must be postmarked by March 31st, at the latest, to be accepted.

Shown smaller than actual size
The saucer measures 139mm in diameter,
the cup measures 63mm in height.

## WORLD WILDLIFE FUND

The World Wildlife Fund was formed to help preserve life in the natural world, and to help safeguard the world's natural environment from irreversible damage. Its scope is the whole of nature.

Since 1961, it has provided grants which have backed over 2000 conservation projects world-wide. It has created or supported 260 national parks on 5 continents—a total area almost twice the size of Texas. The Fund has rescued 33 animal species from the brink of extinction. And it has brought hope of survival to more than 100 other threatened species. There is still more to be done.

The World Wildlife Fund has appointed Franklin Porcelain to service and fulfill all subscriptions to the Hummingbirds of the World collection.

'The Unique Fifty'®

We have a collection of Daylilies called 'The Unique Fifty,' and you can take that name literally. There are fifty mature plants in it, each the result of hand-pollinating fine Daylilies in the hope of getting even better ones. So each plant is unique, the twin of no other. None are named, but all have better pedigrees than most named varieties offered at higher prices. And it should be possible to find two or three plants so lovely you will want to name them after dear friends or loved ones, a nice thing to do.

This is the least expensive way to buy Daylilies, the best low-maintenance perennial for sunny locations. Please order: 'The Unique Fifty.' $65. — plus 10% for handling and prepaid delivery (Conn. residents please add Sales Tax). Orders received after April 10 will be shipped in September. Yes, buy 'The Unique Fifty' with friends to share cost — but shipment must be to only one address.

Buyers will receive our nationally known Gardening Publications Service — Spring and Fall editions of The Garden Book, our catalogues, which really are garden books (there is more in them about how-to-garden than about the 1,200 plants offered), plus three issues of NOTES, an invaluable reminder publication. This service, offered by subscription for $5.00, is sent without charge each year to active customers. We hope you become one.
— Sincerely, Amos Pettingill

**This View of Life** — **by Stephen Jay Gould**

# Death before Birth

*In nature, and in Latin, the exception* probes *the rule*

Can anything be more demoralizing than parental incompetence before the most obvious and innocent of children's questions: Why is the sky blue, grass green? Why does the moon have phases? Our embarrassment is especially acute because we thought we knew the answers perfectly well, but hadn't rehearsed them since we ourselves had received a bumbled response in similar circumstances a generation earlier. It is the things we think we know—because they are so elementary or because they surround us—that often present the greatest difficulties when we are actually challenged to explain them.

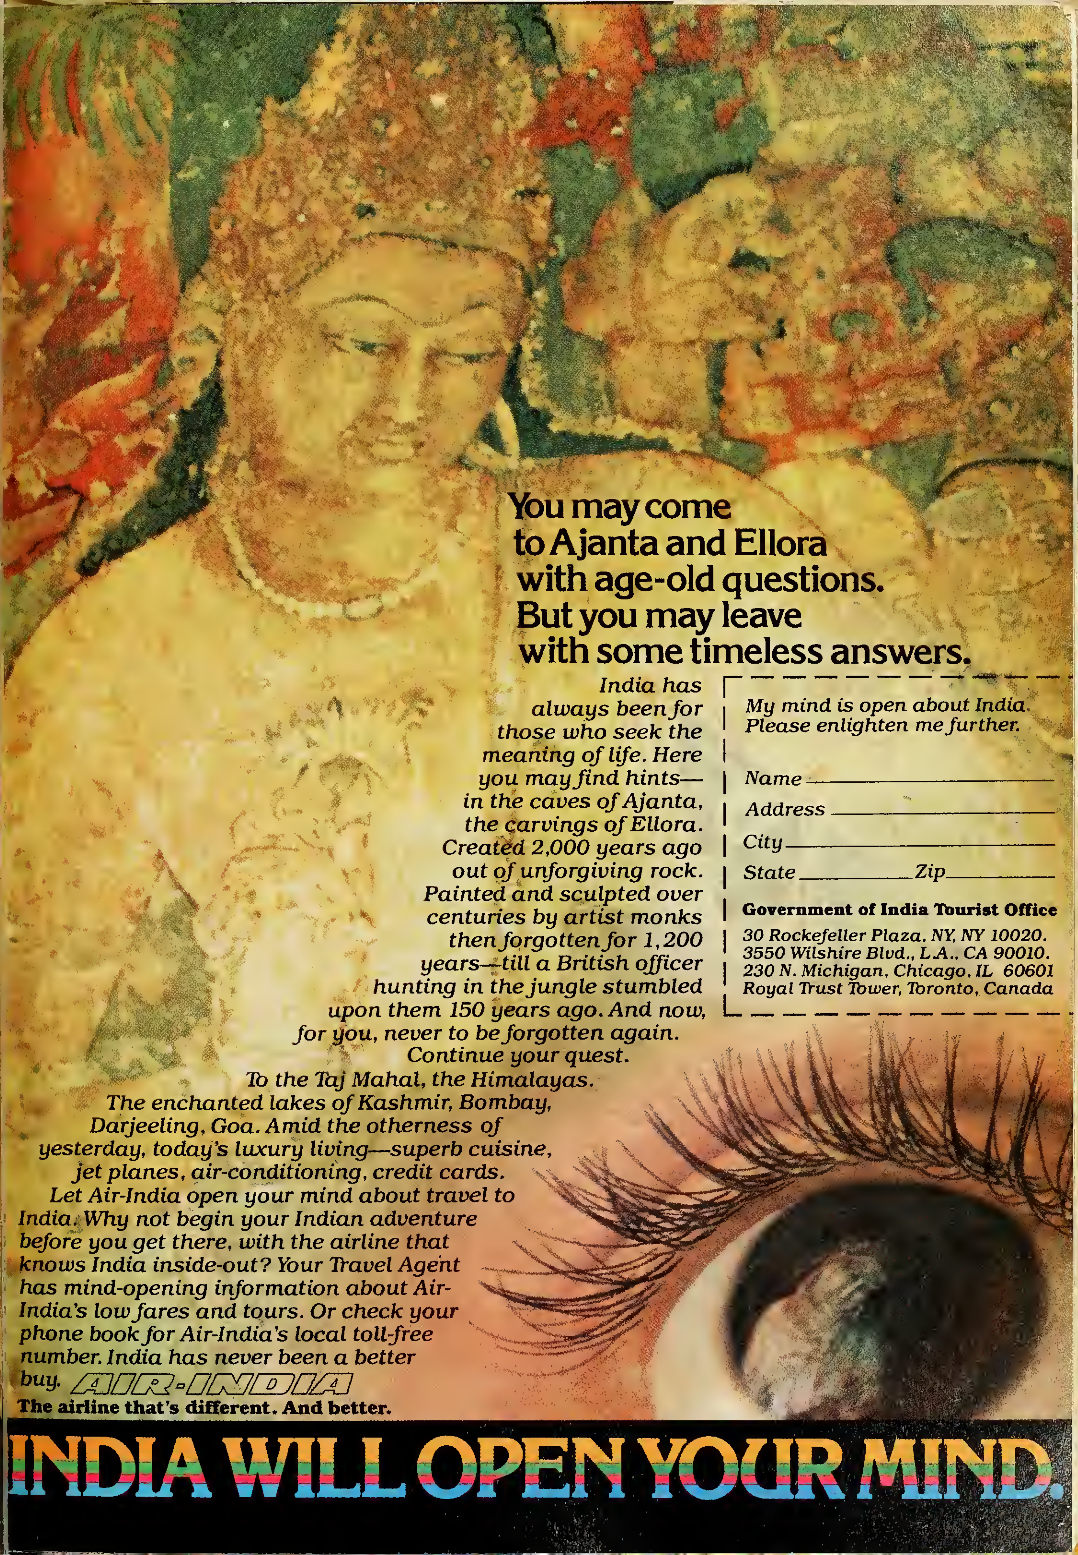
One such question, with an obvious and incorrect answer, lies close to our biological lives: Why, in humans (and in most species familiar to us), are males and females produced in approximately equal numbers? (Actually, males are more common than females at birth in humans, but differential mortality of males leads to a female majority in later life. Still, the departures from a one to one ratio are never great.) At first glance, the answer seems to be, as in Rabelais's motto, "Plain as a nose in a man's face." After all, sexual reproduction requires a mate; equal numbers imply universal mating—the happy Darwinian status of maximal reproductive capacity.

At second glance, it isn't so clear at all, and we are drawn in confusion to Shakespeare's recasting of the simile: "O jest unseen, inscrutable, invisible,/ As a nose on a man's face, . . ." If maximal reproductive capacity is the optimal state for a species, then why make equal numbers of males and females. Females, after all, set the limit upon numbers of offspring, since eggs are so much larger and so much less abundant than sperm—that is, each egg can make an offspring, each sperm cannot.

A male can impregnate several females. If a male can mate with nine females and the population contains 100 individuals, why not make 10 males and 90 females. Reproductive capacity will certainly exceed that of a population made of 50 males and 50 females. Populations made predominantly of females should, by their more rapid rates of reproduction, win any evolutionary race with populations that maintain equality in numbers between the sexes.

What appeared obvious is rendered problematical: Why do most sexual species contain approximately equal numbers of males and females? The answer, according to most evolutionary biologists, lies in a recognition that Darwin's theory of natural selection speaks only of struggle among *individuals* for reproductive success. It contains no statement about the good of the population, the species, or the ecosystem. My previous argument was framed in terms of advantages for populations as a whole—the usual, congenial, and dead wrong way in which most people think of evolution. If evolution worked for the good of populations as a whole, then sexual species would contain relatively few males.

The observed equality of males and females, in the face of obvious advantages for female predominance if evolution worked upon groups, stands as one of our most elegant demonstrations that Darwin was right—natural selection works by the struggle of individuals to maximize their own reproductive success. The Darwinian argument was first framed by the great British mathematical biologist R.A. Fisher. Suppose, Fisher argued, that either sex began to predominate. Let us say, for example, that fewer males than females are born. Males now begin to leave more offspring than females since their opportunities for mating in-



# You may come to Ajanta and Ellora with age-old questions. But you may leave with some timeless answers.

*India has always been for those who seek the meaning of life. Here you may find hints—in the caves of Ajanta, the carvings of Ellora. Created 2,000 years ago out of unforgiving rock. Painted and sculpted over centuries by artist monks then forgotten for 1,200 years—till a British officer hunting in the jungle stumbled upon them 150 years ago. And now, for you, never to be forgotten again.*

ROCKY MOUNTAIN MASTERPIECE

The magnificent cougar, at home in the beauty of the Colorado Rockies, is captured by wildlife artist JAMES E. FAULKNER. When viewing this great work of art, it is easy to feel the crisp autumn air and hear the hypnotic rustling of the golden aspen. Now a special limited edition four color lithograph printed on heavy 100% rag paper.

THIS EDITION IS LIMITED TO ONLY 500 PRINTS
EACH SIGNED AND NUMBERED BY THE ARTIST.

$75.00 per print (unmounted)

crease as they become rarer—that is, they impregnate more than one female on average. Thus, if any genetic factors influence the relative proportion of males born to a parent (and such factors do exist), then parents with a genetic inclination to produce males will gain a Darwinian advantage—they will produce more than an average number of grandchildren thanks to the superior reproductive success of their predominantly male offspring. Thus, genes that favor the production of males will spread and male births will rise in frequency. But this advantage for males fades out as male births increase and it disappears entirely when males equal females in number. Since the same argument works in reverse to favor female births when females are rare, the sex ratio is driven by Darwinian processes to its equilibrium value of one to one.

But how would a biologist go about testing Fisher's theory of sex ratio? Ironically, the species that match its predictions are no great help beyond the initial observation. Once we frame the basic argument and determine that the species we know best have equal numbers of males and females, what do we achieve by finding that the next thousand species are similarly ordered? Sure, it all fits, but we do not gain an equal amount of confidence each time we add a new species. Perhaps the one to one ratio exists for another reason?

To test Fisher's theory, we must look for exceptions. We must seek unusual situations in which the premises of Fisher's theory are *not* met—situations that lead to a specific prediction about how sex ratio should depart from one to one. If change of premises leads to a definite and successful prediction of altered outcome, then we have an independent test that strongly boosts our confidence. This method is embodied in the old proverb that "the exception proves the rule," although many people misunderstand the proverb because it refers to the less common meaning of "prove." Prove comes from the Latin *probare*, "to test" or "to try." Its usual, modern meaning refers to final and convincing demonstration and the motto would seem to say that exceptions establish indubitable validity. But in another sense, closer to its root, "prove" (as in "proving ground" or printer's "proof") is more like its cognate "probe," a test or an exploration. It is the exception that probes the rule by

testing and exploring its consequences in altered situations.

Here nature's rich diversity comes to our aid. The stereotyped image of a birder assiduously adding the rufous-crowned, peg-legged, speckle-backed, cross-billed, and cross-eyed towhee to his life list gives, in unwarranted ridicule, a perverted twist to the actual use made by naturalists of life's diversity. Nature's richness permits us to establish a science of natural history in the first place, for the variety virtually guarantees that appropriate exceptions can be found to probe any rule. Oddities and weirdnesses are tests of generality, not mere peculiarities to describe and greet with awe or a chuckle.

Fortunately, nature has been profligate in providing species and modes of life that violate the premises of Fisher's argument. In 1967, British biologist W.D. Hamilton (now at the University of Michigan) gathered the cases and arguments into an article entitled "Extraordinary Sex Ratios" (*Science*, April 28, 1967). I will discuss in this column only the clearest and most relevant of these probing violations.

Nature rarely heeds our homilies in all cases. We are told, and with good reason, that mating of brothers and sisters should be avoided, lest too many unfavorable recessive genes gain an opportunity to express themselves in double dose. (Such genes tend to be very rare, and chances are small that two unrelated parents will both carry them. But the probability that two sibs carry the same gene is usually 50 percent.) Nonetheless, some animals never heard the rule and indulge, perhaps exclusively, in sib mating.

Exclusive sib mating destroys the major premise of Fisher's argument for one to one sex ratios. If females are always fertilized by their brothers, then the same parents manufacture both partners of any mating. Fisher assumed that males and females had different parents and that an undersupply of males awarded genetic advantages to those parents that could produce males preferentially. But if the same parents produce *both* the mothers and fathers of their grandchildren, then they have an equal genetic investment in each grandchild, no matter what percentage of males and females they produce among their children.

In this case, the reason for an equal balance of males and females disappears and the previous argument for female predominance reasserts itself. If each pair of grandparents has a limited store of energy to invest in offspring, and if grandparents producing more offspring gain a Darwinian edge, then grandparents should make as many daughters as possible, and produce only enough sons to insure that all their daughters will be fertilized. In fact, if their sons can muster sufficient sexual prowess, then parents should make just one son and use every bit of remaining energy to produce as many daughters as they can. As usual, bountiful nature comes to our aid with numerous exceptions to probe Fisher's rule: indeed, species with sib mating also tend to produce a minimal number of males.

Consider the curious life of a male mite in the genus *Adactylidium*, as described by E.A. Albadry and M.S.F. Tawfik (*Annals of the Entomological Society of America*, 1966, p. 458). It emerges from its mother's body and promptly dies within a few hours, having done apparently nothing during its brief life. It attempts, while outside its mother, neither to feed nor to mate. Now we know about creatures with short adult lives—the mayfly's single day after a much lengthier larval life, for example. But the mayfly mates and insures the continuity of its kind during these few precious hours. The males of *Adactylidium* seem to do nothing at all but emerge and die.

To solve the mystery, we must study the entire life cycle and look inside the mother's body. The impregnated female of *Adactylidium* attaches to the egg of a thrip. That single egg must provide the entire source of nutrition for generating all her offspring, for she will feed on nothing else before her death. This mite, so far as we know, engages exclusively in sib mating; thus, it should produce a minimal number of males. Moreover, since total reproductive energy is so strongly constrained by the nutritional resources of a single thrip's egg, progeny are strictly limited, and the more females the better. Indeed, *Adactylidium* matches our prediction by raising a brood of five to eight sisters accompanied by a single male who will serve as both brother and husband to them all. But producing a single male is chancy; if he dies, all sisters will remain virgins and their mother's evolutionary life is over.

If the mite takes a chance on producing but a single male, thus maximizing its potential brood of fertile females, two other adaptations might lessen the risk—providing both protection for the male and guaranteed proximity to his sisters. What better than to rear the brood entirely within a mother's body, feeding both larvae and adults within her, and even allowing copulation to occur inside her protective shell. Indeed, about forty-eight hours after she attaches to the thrip's egg, six to nine eggs hatch within the body of a female *Adactylidium*. The larvae feed on their mother's body, literally devouring her from inside (much like the gall midges I discussed in December 1976). Midges are insects, but mites belong to a different group (Acarina) within the phylum Arthropoda. Thus, the similarities of rearing are convergent; they reflect separate evolution, not common descent.

Two days later, the offspring reach maturity, and the single male copulates with all his sisters. By this time, the mother's tissues have disintegrated, and her body space is a mass of adult mites, their feces, and their discarded larval and nymphal skeletons. The offspring then cut holes through their mother's body wall and emerge. The females must now find a thrip's egg and begin the process again, but the males have already fulfilled their evolutionary role before "birth." They emerge, react however a mite does to all the glories of the outside world, and promptly die.

But why not carry the process one stage further? Why is the male born at all? After copulating with his sisters, his work is done. He is ready to chant the acarine version of Simeon's prayer, *Nunc dimittis*—"Lord, now lettest thou thy servant depart in peace." Indeed, since everything that is possible tends to occur at least once in the multifarious world of life, a close relative of *Adactylidium* does just this. *Acarophenax tribolli* also indulges exclusively in sib mating. Fifteen eggs, including but a single male, develop within the mother's body. The male emerges within his mother's shell, copulates with all his sisters, and dies before birth. It may not sound like much of a life to us, but the male *Acarophenax* does as much for its evolutionary continuity as Abraham did in fathering children into his tenth decade. Nature's oddities are more than good stories. They are material for probing the limits of interesting theories about life's history and meaning.

*Stephen Jay Gould teaches biology, geology, and the history of science at Harvard University.*

# Sacred Dances of Bhutan

*An ancient tradition of festival drama*
*is the protective ritual of a Buddhist kingdom*

**by Michael Aris**

By chance, the first two British political missions to reach the remote kingdom of Bhutan in the eastern Himalayas, in the years 1774 and 1783, arrived at the time of the annual *Dromchö* festival held in the summer capital at Thimphu. "The whole together presented a collection of more fiendlike visages than ever painter represented in the temptation of Saint Antony, and the wild and clamorous sound of the instruments seemed well adapted to make such devils dance," wrote one of the observers, recording the first Western contacts with a rich and complex tradition, which later travelers discovered thriving in all those regions throughout Asia where Northern (Tibetan) Buddhism, or Lamaism, prevailed. Failing to understand this tradition in the context of history and Buddhist doctrine, the early observers were baffled by what appeared to be a macabre and sinister spectacle. They could not appreciate its significance for the Bhutanese peasants who watched the dances (*cham*) against the magnificent backdrop of temple or fortress.

Bhutan is today the only independent country where Northern Buddhism survives as the state religion. The performance of sacred dance as a state ritual by trained monks and laymen in the national and provincial capitals has all the support of the government and royal family. At the same time, quite independent of official patronage, several festivals of sacred dance take place in local temples and monasteries in Bhutan, just as they do in other Himalayan regions untouched by Communism from the north, reminding us that the whole tradition has its origins in a private, indeed secret, initiatory experience that has nothing to do with governments.

How do we explain the basic paradox of dance in a religion whose most powerful symbol is the Lord Buddha sunk in concentrated immobility, a religion that has always prohibited music and dancing for its ordained disciples. The answer is found in the whole development of Mahayana ("greater vehicle") Buddhism, which saw the incorporation of many ritual and meditative techniques belonging to older, non-Buddhist traditions. If these could be adapted to the Buddhist aim of escaping from the round of phenomenal existence by severing the root of the "self," then they were easily validated and absorbed under the heading of "skillful means."

---

The **Royal Dancers and Musicians of Bhutan** will end their United States tour with a performance in the American Museum of Natural History's Auditorium, at 3:00 P.M., on April 27. For tickets call (212) 873-1327. For a complete schedule of the troupe's tour, contact the sponsors, The Asia Society's Performing Arts Program, 133 East 58th Street, New York, N.Y. 10022.

---

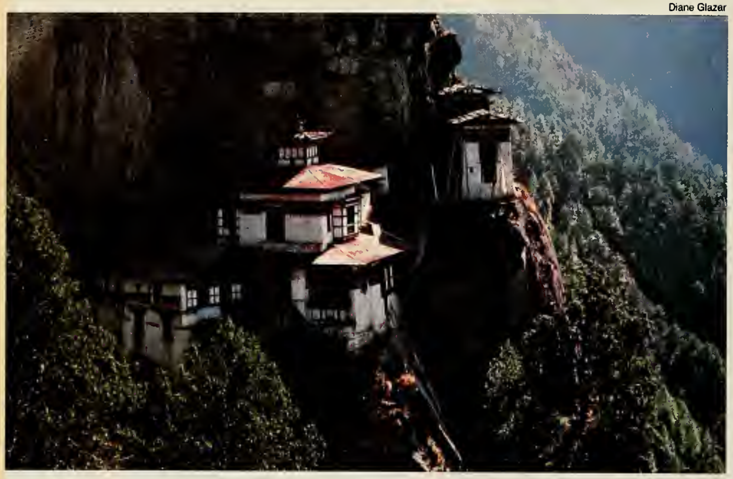
This process partly accounts for the presence of large sections of the Hindu pantheon in Northern Buddhism and for the survival of many pre-Buddhist deities of specifically Tibetan origin, all with their primary characters more or less neutralized in the interests of the nontheistic nature of Buddhism. These myriad sets of gods and their attendants acquired a supportive role, interpretable on several different levels of reality. Ultimately, they were seen to arise from, and dissolve back into, the universal matrix of the "Void." It became the meditator's task to identify himself with a deity to such a degree that he realized in himself this process of creation and dissolution, thus freeing himself of its mastery and the perverted view of reality that marks human existence.

The deity that is made the object of meditation is usually the one associated with the meditator's particular school of Buddhism or the one favored by his own teacher, although in some cases it can be a matter of individual choice. One of the principal ways of achieving union with the chosen deity is through the repetition of a mantra, a string of syllables that contains the deity's essence, while at the same time visualizing the form of the deity in the center of a mandala, a diagram of the deity's heaven as it is conceived to

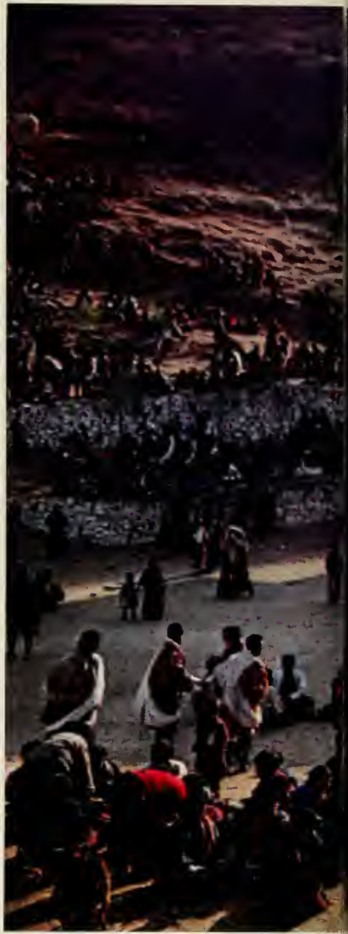
*While the ritually important dances are the domain of monks versed in the sacred tradition, trained laymen, right, perform many of the auxiliary dances featured in national and local festivals.*

Ernst H

Diane Glazer



The Tagtshang monastery in Paro, above, is associated with the deified Indian sage Padmasambhava, who, according to legend, introduced Buddhism to Bhutan and Tibet. It is in his heaven that some of the sacred dances are supposed to have been revealed to their composers, who traveled there in a dream or trance. Right: Padmasambhava is depicted in the *T'ongdröl* tapestry in Paro, believed to offer enlightenment to those who view it.



exist both within and outside the body of the meditator. The initiate supplements these verbal and mental exercises by taking on the physical attributes of the deity as expressed in a mudra, a code of gestures that likewise summons the essential nature of the god. The deity in his heaven is often conceived as performing a divine dance, and there seems little doubt that dancing as the god incarnate originated as one of the secret experiences that those initiated into the esoteric traditions of Buddhism, the tantras, had to learn from their master. The Hevajra Tantra explains:

> Dancing as Śrī Heruka with mindful
> application, undistracted,
> Meditating with thought impassioned,
> the mind uninterrupted in its
> concentration,
> Buddhas and masters of the Vajra-
> doctrine, goddesses and yoginis,
> Sing and dance to their utmost in
> this song and dance.
> There comes thereby protection for
> the troupe and protection for
> oneself. Thereby the world is
> reduced to subjection.

Among the cultural achievements of the Lamaist world, the origin and history of sacred dance are perhaps the least documented. There is as yet no means of knowing whether the tradition was transmitted from India by tantric masters or whether it arose spontaneously in Tibet in reaction to the written descriptions of heavenly dance contained in tantric literature. What is sure is that the performance of sacred dance as a public show only became part of monastic curriculum after a great deal of hesitation and some misgiving. Even today, the upholders of the tradition insist that the dances must not be performed as a worldly spectacle, and there are still a few monks and scholars who go so far as to decry the very nature of these rites.

For the great majority of religious practitioners, however, the dances are an indispensable part of certain annual rituals. They are a dramatic extension of the liturgy, constituting the "generation of the deity in front," that is, externally, which follows upon the "generation of the deity in oneself" accomplished as a ritual in the main temple by the assembled monks. Both stages, internal and external, revolve around the creation of the deity's mandala, a circumscribed area rendered safe from hostile influences into which the god is led by his divine attendants. In the liturgical ritual, the mandala is a painted, sometimes three-dimensional physical object. The main section of the dance, consisting of clockwise circular movements, echoes the formal structure of the painted mandala. This is preceded and followed by phases of creation and dissolution.

As portrayed in many dances, the deity is basically compassionate but has assumed a wrathful appearance to counter evil influences that cannot be subdued by peaceful means. The climax of most dances dedicated to the wrathful deities occurs when an effigy representing evil is stabbed and dismembered in an act of ritual murder. Sometimes this is realistically performed, with the blood-filled intestines of an animal extracted from a dough figurine and cast in all directions. The base nature of the evil power is thus

Michael Ans

annihilated, while the conscious principle is released to a heaven—until the following year.

On one level of interpretation, it is the "self" that is thus destroyed. The more usual view holds that what is destroyed are the forces opposing Buddhism in general or opposing a particular school of Buddhism. This belief helped to give the dance its place in state and community ritual. A whole cycle of Tibetan sacred dances known as the Black Hat, which is also very popular in Bhutan, is said to imitate the movements with which the Tibetan monk Pelgi Dorje sought to distract the anti-Buddhist king Lang Darma before assassinating him in A.D. 842. The Black Hat dances and all the other dances whose purpose is the destruction of evil are performed for the sake of the whole nation or for a particular district in annual festivals of renewal and rededication.

Two major streams can be discerned in the development of sacred dance; both are represented in the Bhutanese tradition. The first is mainly associated with the *Nyingmapa* ("old order") school, dating from the twelfth or thirteenth century. It depended on visionary revelations—a source now considered dormant—for the authority of the sacred dances. In a dream or trance the composer would travel to the realm of the deified Indian sage Padmasambhava, and on his return he would teach his disciples the heavenly dances he saw performed there. The second stream is associated more with the later schools, which sought to rubricate and codify those dances inherited from the older schools, including the *Nylingmapa*, that could be regarded as authentic in origin.

Both the revelational and codifying traditions depended on dance manuals (*chamyik*) to record the dances for posterity. These texts are never used for the purposes of practical study, however; they serve instead to remind the chief exponents in case of doubt. Separated from the living tradition of personal instruction, they are as incomprehensible as the notation found in Tibetan musical scores. Not only the steps of the dance but the whole process of meditative visualization has to be learned directly from a master (*champön*).

Certain mnemonic devices, such as counting out the rhythm, are employed to help the student memorize the complicated steps. If one considers that many festivals continue for up to six days with very few breaks, some idea is gained of this prodigious feat, yet it forms only one small part of the entire curriculum of study. A story found in the biography of the sixth Dalai Lama (of Tibet) tells how, as a boy, he had to watch his dance master perform in snow so that by observing his footprints he could memorize all the different "thunderbolt steps," a technique of study peculiar to the *Gelukpa* school at that time. The Dalai later chastised himself for having watched the performance merely as a show.

Long before Bhutan achieved its unification and independence in the middle of the seventeenth century, it had developed its own sacred dance traditions associated with the great saint Pema Lingpa (1450–1521), the ancestor of the present royal family. His autobiography contains several vivid passages describing the visions he had of the dances performed in Padmasambhava's heaven. Today, the extensive repertoire credited to Pema Lingpa has an auxiliary function in all the major festivals and never forms the principal item. His dances provide interludes before and after the ritual climax centering on the deity invoked in the mandala. Many of Pema Lingpa's compositions portray different sets of divine attendants and acrobats, who prepare a path to heaven.

Some of these dances have strong shamanistic overtones derived from a stratum of pre-Buddhist tradition centering on the village oracle and his state of possession or flight to heaven. Certain of Padmasambhava's divine attendants are known as *pawo*, the common name for the village oracle in Bhutan. An oracle, accompanying himself on the pellet drum, performs the steps of a snow cock before falling into a trance and receiving the god into his body. Pema Lingpa's ceremonial version of this rite has two pairs of heavenly *pawo* imitating the steps of the village oracle; the dance is commonly performed to welcome distinguished guests to a palace or fort, conceived here as a heaven.

The shaman's drum is also used in the Drum Dance of Dramitsé, attributed to Pema Lingpa's son Kunga Wangpo, who saw it in heaven and had it performed to consecrate a temple at Dramitsé in eastern Bhutan. As in the case of several other dances, the performers wear a variety of animal masks made of wood or papier-mâché. The strange spectacle can have a grace and dignity all its own even though there are no opportunities to depart from, or improvise on, its immutable form.

Sacred dance certainly had its place in the complex of emotions, ambitions, and reactions that were released in the quest for Bhutanese sovereignty. Although it had long been fragmented into a number of clan territories and ecclesiastical principalities, the country achieved unification despite the concerted opposition of successive Tibetan regimes. This was accomplished mainly through the efforts of the great monk and scholar-statesman *Shabdrung* Ngawang Namgyal, who arrived in western Bhutan as a refugee in 1616. Hereditary prince-abbot of the powerful *Drukpa* ("thunder dragon") sect of the *Kagyüpa* school (the school of "oral transmission"), he consolidated the *Drukpa* hold on the western region. His immediate successors extended the borders to their present limits, and after much difficulty, a theocracy was established, with the incarnations of the founding *Shabdrung* (Bhutan's equivalent to the Dalai Lama of Tibet) acting as titular heads of state. Temporal authority was delegated to the office of the *Druk Desi*. The British came to know the two incumbents as the *Dharma Raja* ("king of religion") and the *Deb Raja* ("regent"). (Both offices disappeared after the present hereditary monarchy became established early in this century, and the present *Shabdrung* incarnation does not reside in the country.)

The country was ruled from the huge capital and provincial fortresses (*dzong*) that dominate the major val-

*Performances by monks, below and right, became accepted ritual practice, despite the reservations of some Buddhist scholars. The royal dance troupe now on world tour, however, consists only of lay dancers.*

Ernst Haas

leys to this day. In these imposing structures were housed communities of state monks dedicated to the ruling *Drukpa* school, and many government officers were drawn from the country's large monastic population. Some rose from the ranks of the lay servitors, or retainers, attached to each *dzong*. Despite their lay status, they were required to observe a semimonastic code of discipline. The institutions developed under the theocracy penetrated to every region of the country and affected every facet of its subjects' lives.

The triumph of the ruling *Drukpa* sect (which ultimately gave the country the name used by the Bhutanese themselves—*Drukyul*) is traditionally ascribed to the sect's hold over its guardian deities and, particularly, to the intimate relationship that the founding *Shabdrung* is supposed to have had with them. How else, it is claimed, could the Bhutanese have repulsed no less than six Tibetan invasions during the lifetime of the *Shabdrung*, and many more thereafter. There is little doubt that *Shabdrung* Ngawang Namgyal himself used the destructive forces of sacred dance in acts of sympathetic magic directed against the enemy rulers of Tibet. One incident recalled in his official biography tells how he took the lead in a dance dedicated to the chief protective deity Mahākala. Waving a banner "like the black cloud blowing from the vault of the sky at the end of time," he danced to the center of the courtyard and there consigned to a triangular pit a list containing the names of his enemies, "so that he radiated a great brilliance which terrified all those who stood close by."

The Mahākala ritual later formed the basis of the New Year festival that is still held in the old winter capital at the fortress of Punakha. The masked dances, known as the *Punakha Dromchö*, last for five days, and their special feature is the formal role adopted by selected laymen from eight villages who act the part of a ceremonial militia, the successor of the *Shabdrung*'s personal army. They provide a scene of extraordinary medieval panoply, further enriched on the last day by a long monastic procession to the banks of the P'o-chu River. There, the head abbot in the costume of the Black Hat offers to the serpent spirits pieces selected from all the mandalas that have been consecrated by the monks throughout the year. The apparel of the abbot on that occasion reminds one of temple paintings that show the *Shabdrung* in his wrathful aspect performing a dance of destruction in the Black Hat costume.

The uncompromising figure of the founding *Shabdrung* looms over many of the Bhutanese sacred dances and the stories surrounding them. One typical legend tells how the Mahākala dance of the *Legön Tsokhor* happens to lack a finale: While providing appropriate accompaniment with cymbals from his throne, the *Shabdrung* once summoned a dancing emanation of this god to bring him the soul of the enemy ruler of Tibet, but the chief minister, who was peeping from behind a curtain, disturbed the god, causing him to disappear before the completion of the dance.

The festival of the *Punakha Dromchö* established by the *Shabdrung* as the official New Year celebrations of the government later served as a model for the summer festival introduced to the summer capital (now the permanent capital) at Thimphu. While the *Punakha Dromchö* centers on the deity Mahākala, the *Thimphu Dromchö* is appropriately dedicated to the god's consort, Śrī Devī ("glorious goddess"), and it ends with three days given over to the worship of the deified saint Padmasambhava, who has so many legendary associations with Bhutan. Underlining Padmasambhava's importance for the Bhutanese is the fact that in all the provincial fortresses and in several private monasteries, it is the dances dedicated to him that take up their festivals. Thus, while the capital region concerns itself mainly with protective rites to guard the state at large, the provinces turn to the more conciliatory figure of Padmasambhava and his eight aspects, all of whom appear robed and masked on the final day of each festival to give their blessings to the public. On occasion, gigantic appliquéd tapestries depicting Padmasambhava are raised to form an extraordinary backdrop. Objects of great devotion, they are known by the

special term *t'ongdröl,* "liberation by sight."

Many of the auxiliary dances performed in the festivals are directed toward the edification of the audience rather than the achievement of a ritual goal. Today a professional touring group of trained laymen generally performs these dances, but previously the dancers were recruited from among the lay servitors attached to each fortress. Some of the richest and most interesting items from the Bhutanese repertoire belong to this category of "attendants' dances" (*böcham*), including all those attributed to Pema Lingpa outlined above.

Most didactic in purpose is perhaps the Red Dance of the *Rakshas,* which derives from the same tradition as the famous Tibetan Book of the Dead. The Lord of Death presides over a court that judges a man for his past actions. His release from samsara, or future rebirth, is determined by how he reacts to the fearful apparitions who are the god's retinue, actually his own karmic projections. Another dance drama, whose purpose is to engender a feeling of faith and renunciation, enacts the story of how the poet-saint Milarepa (1040–1123) saved a deer from a hunter whom he subsequently converted to a life of religion.

On a more mundane level, the sung and mimed dance of *P'olé Molé* ("the good man and the good lady") is concerned with the virtues of marital fidelity and derives from a Tibetan tale that stems ultimately from an Indian tradition.

A poignant survival in this category of auxiliary dances is *Chözhé* ("dharma song"), the dance of the old monastic bodyguard of the *Drukpa.* It is supposed to be based on an incident in the life of the sect's founder when he countered the supernatural forces opposing him on his journey to open up the pilgrim route to the sanctuary of Tsari in southeast Tibet. The slow and stately gestures of stylized subjugation performed in perfect unison by laymen dressed as warrior monks seem to convey something of the essence of the Bhutanese tradition, which has always striven for harmony between its secular and spiritual ideals.

No performance is complete without a clown (*atsara*), whose business it is to provide light relief by ridiculing the sacred dances, performing obscene jokes, and acting as stagehand. He represents an aberrant figure who arose from the national subculture only to be absorbed by the traditional order. He is comic but at the same time deeply serious, for he stands ultimately for unity and balance. His mask and name show him to be an Indian teacher—a figure of fun because he is an Indian with a big nose, but sacred because he is a teacher.

Are the guardians of Buddhist orthodoxy shaking their heads dolefully in some distant heaven of pure dance as they look down on all these developments? In the Bhutanese experience alone, the presiding authority for sacred dance has filtered down a line stretching from tantric yogis to a reincarnating theocrat and thence to the hereditary Buddhist monarch of today. More and more folk elements and local cults have gradually been brought in, turning the spectacle outward toward the audience and away from its meditative core. Few dancers now achieve that perfect balance of body, speech, and mind that is said to be the prerequisite for sacred dance. But what remains is a vital and enriching experience, for while the dancers may know they are not gods, there still remain spectators who sometimes see their gods come alive. □

# Toad Sanctuary in a Tarantula Burrow

*A snake that tries to make a meal of a tiny toad may have to face the fearsome defense of a huge spider*

**by R. Howard Hunt**

A western ribbon snake, its forked tongue flicking, slipped through boulder-strewn prairie grass hunting for prey. Abruptly, it paused at a limestone slab and began to flick its tongue more rapidly, sampling the air for the chemical cues that would tell it a toad was near. Nearby, a narrow-mouthed toad dipped and darted about a small hole from which a ceaseless stream of ants flowed. Its attention was riveted upon the hole and the delectable ants. Suddenly, a striped blur hit the nickel-sized toad, engulfing it almost instantly. As the ribbon snake's jaws enveloped the toad's entire body, the doomed animal kicked and struggled, but the quivering bulge moved farther and farther down until it was only a muscular ripple carrying the small morsel to the snake's stomach.

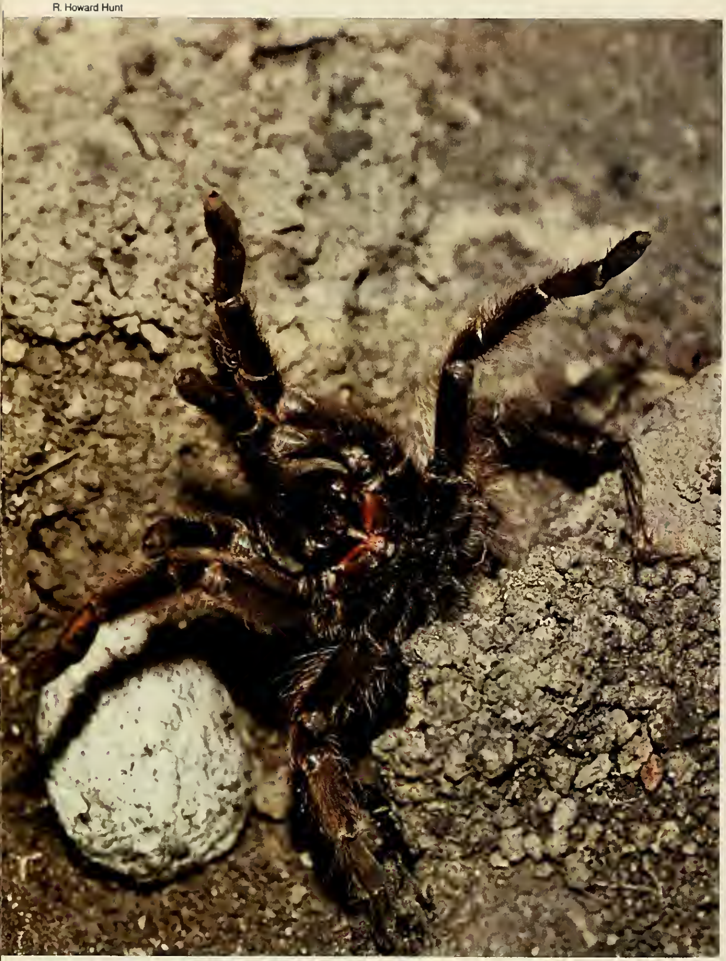
Undetected by the ribbon snake, a second narrow-mouthed toad hunched hard against one flat edge of the limestone slab. The toad had seen the approaching snake and had stopped dead still, its pointed snout pressed into the soil. But the sham did not work, for the snake again slithered forward toward the small, brown lump that was the toad. The lump stirred, then bounded to the only escape possible—a burrow beneath the slab.

Sensing another meal, the ribbon snake followed the toad's scent trail, which led to the entrance of the burrow. And just beyond, at the edge of darkness, crouched the toad. With lidless eyes fixed on its prey, the snake tensed for a lunge. Suddenly a great hairy body, propelled by eight hairy legs, burst from the depths of the burrow, and a fully mature, female tarantula scuttled to within an inch of the toad. Taking advantage of the situation, the toad fled to safety—beneath the imposing black fangs of the tarantula. The confused snake reversed itself and disappeared into the waving grass. Danger past, the narrow-mouthed toad *Gastrophryne olivacea* wriggled from under its burrow companion, the giant tarantula, *Dugesiella hentzi*.

In my youth, I tramped the grasslands west of Fort Worth, Texas, observing these fascinating mygalomorph spiders. One of my favorite haunts was a narrow tract of land crossed by a shallow creek and railroad tracks. Construction workers on the latter had ripped a vast number of 100-million-year-old limestone rocks from their bed and onto the flat prairie. When I spotted a likely rock, I flipped it over and often uncovered a startled

*At the approach of a western ribbon snake, a narrow-mouthed toad scuttles toward the safety of a female giant tarantula. Instead of a toad, the snake will get a faceful of spider feet and fangs.*

R. Howard Hunt



*A female tarantula will defend her egg case at any sign of disturbance. Normally aggressive, she is particularly ferocious while her eggs are incubating.*

tarantula, which instantly raised its fangs in a very threatening manner. I knew that *Dugesiella*'s weak venom presents no real threat to humans. At times, however, an annoyed tarantula displays another defense tactic: using its fourth pair of feet, it brushes irritating hairs from its dorsal abdomen. Festooned with barbs and reverse barbs, and nearly impossible to work out once embedded, these hairs hang in the air, close by the tarantula, waiting for the eyes, nostrils, and mouth of any audacious attacker. (Expended hairs are replaced during molting, when the tarantula splits out of its exoskeleton and emerges with a fresh skin.)

Considering the tarantula's irascible nature, I was all the more amazed when I found up to five western narrow-mouthed toads in the same shallow burrow with it. When I lifted the sheltering rock from a burrow containing both toads and tarantula, the toads dived under the spider, which assumed a threatening fangs-up posture. As the tarantula moved in response to me, so did the toads. Repeatedly, they squirmed and wedged beneath the shifting tarantula. The panic ended when I gently replaced the rock over the unlikely group.

After a ten-year absence from Fort Worth and the tarantulas, I returned in the spring of 1975, determined to learn more about the strange relationship between toad and tarantula. Intending to re-create in a laboratory situation what I found in the field, I collected several tarantulas, along with their associated rocks, soil, and toads. Under one platter-sized fossil ammonite, I found more than I had expected: six adult narrow-mouthed toads; the chitinous remains of pill bugs, millipedes, crickets, and beetles; an old tarantula egg case; the molt of an adult tarantula; a lizard skeleton; and a large female tarantula, measuring almost two inches from fangs to abdominal spinnerets. Although I usually assign numbers to study animals, I thought it appropriate to name this tarantula Ammonita, in honor of her unusual shelter. Returning to the laboratory, I reunited Ammonita with her toads in a terrarium, two by four by two feet deep.

Ammonita immediately started a burrow under the fossil. Working several nights like a minibulldozer, scooping out and carrying clods of earth with her versatile fangs, she excavated a spacious burrow six inches long and lined the entrance with silk. Fortunately for my observations, the burrow had no bends or obstructions, and with the aid of a penlight, I could see its entire length.

As I had hoped, the toads moved in with Ammonita and soon a routine developed. In the evenings, the tarantula waited motionless at the mouth of the burrow, ready to snatch a passing insect, and one by one the six toads brushed by her and skulked around the periphery of the fossil. Once or twice a week, Ammonita satiated her modest appetite with a single cricket or beetle, which she quickly reduced to a sticky pellet between her fangs. The toads, however, required seemingly infinite amounts of termites and ants; on one occasion a tiny male lapped up twenty fire ants within five minutes.

Because of its tough and toxic skin, a narrow-mouthed toad can wallow freely among ants. But the distasteful skin does not repel all snakes: the western ribbon snake, *Thamnophis proximus*, can devour a dozen toads in short order.

One evening, I released a twenty-inch ribbon snake into Ammonita's terrarium. As usual, the tarantula stood at the entrance of her burrow, and the toads foraged nearby. The snake soon neared the burrow, but the toads hopped toward their protector and the tarantula held her ground. At the moment of truth, only one toad remained under Ammonita, the rest having fled to the innermost recesses of the burrow. With one back foot resting lightly on the head of the toad, Ammonita slowly raised her fangs. The snake, evidently sensing no danger in this, crawled closer to the entrance, then tried to inch past Ammonita. Suddenly, the tarantula jabbed with feet and fangs. Startled, albeit uninjured, the snake sped out of the burrow and away from the thing lurking within.

In July, I gave Ammonita a mate, and a handsome one at that: he had splendid long legs, an auburn abdomen, and on either side of his gracefully curved fangs, a club-shaped pedipalp. At the tip of each pedipalp, a mature male tarantula possesses a bulblike syringe containing microscopic, sperm-packed capsules. This sexual structure develops after the last molt and signals an end, usually within months, to the male's life span of one decade. But before dying, he abandons his sedentary life and wanders far afield searching for a mate.

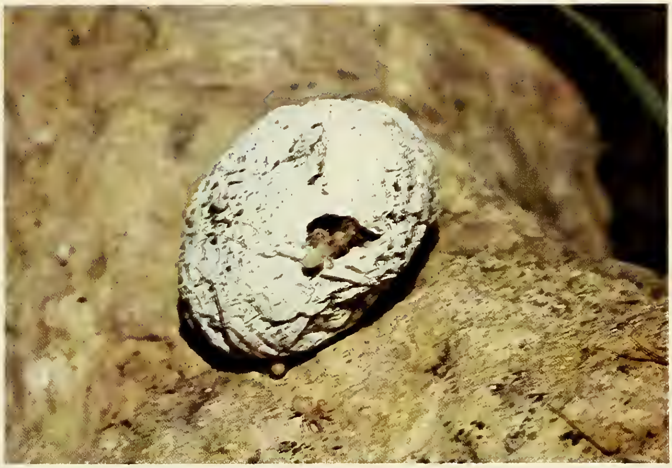
In his investigation of the terrarium, Ammonita's mate-to-be passed the silk-swathed hole beneath the fossil. His feet touched the silk and jerked spasmodically; his pedipalps rapped against the hard soil. Ammonita rushed him. He held her off by locking the hooks on his first pair of legs into her fangs and forced her into a nearly vertical position. Working rapidly now, he rhythmically brushed his pedipalps against Ammonita's sternum, then injected sperm into her genital pore. Immediately afterward, I removed the male to another terrarium where he quickly aged over the next several weeks. His movements became progressively feeble, and one entire leg dropped off at the joint. His purpose past, the male died one month after the mating.

But Ammonita continued lively as usual until October when she pushed soil across the entrance of the burrow until it was blocked. Soon the temperature in the unheated terrarium would cool to 45° to 50° F. The rate of metabolism of the poikilothermic tarantula and toads would then be reduced, allowing them to hibernate in the darkness of their sealed burrow.

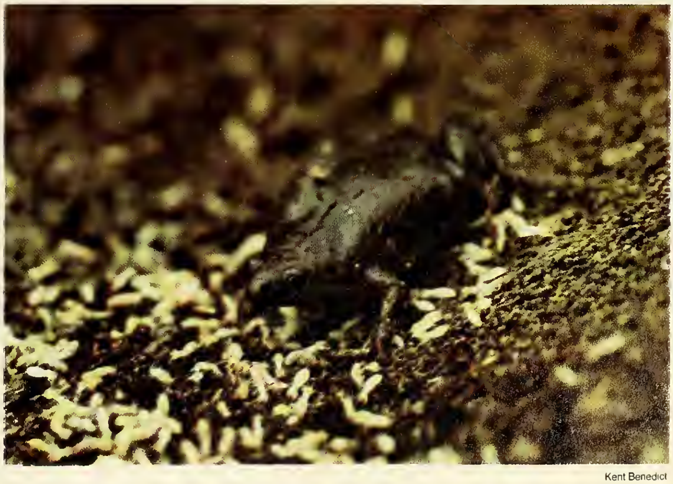
April 3, 1976. Ammonita and her toad companions emerged from hibernation. In the following weeks and months previous behavior patterns were renewed with one exception: Ammonita was even more aggressive when chasing introduced snakes. As usual, the toads had the run of the burrow; frequently, while moving about, they squeezed past her rapidly swelling abdomen.

May 31. Deep within the burrow, Ammonita began a silken bag that was to contain her eggs. She spun thicker

*Baby tarantulas begin to pour out of a hole they have ripped in the silken sack that has encased them for months, top. Hundreds of spiderlings are born at a time, after which they mill about their mother's burrow. Because their hairs are barbed, they have nothing to fear from their burrow cohabitants, the narrow-mouthed toads. In a terrarium experiment, bottom, termites were dropped into a tarantula burrow among the milling spiderlings. The toads preyed only on the termites and spit out any baby tarantulas that they inadvertently struck with their tongue.*



R. Howard Hunt



Kent Benedict

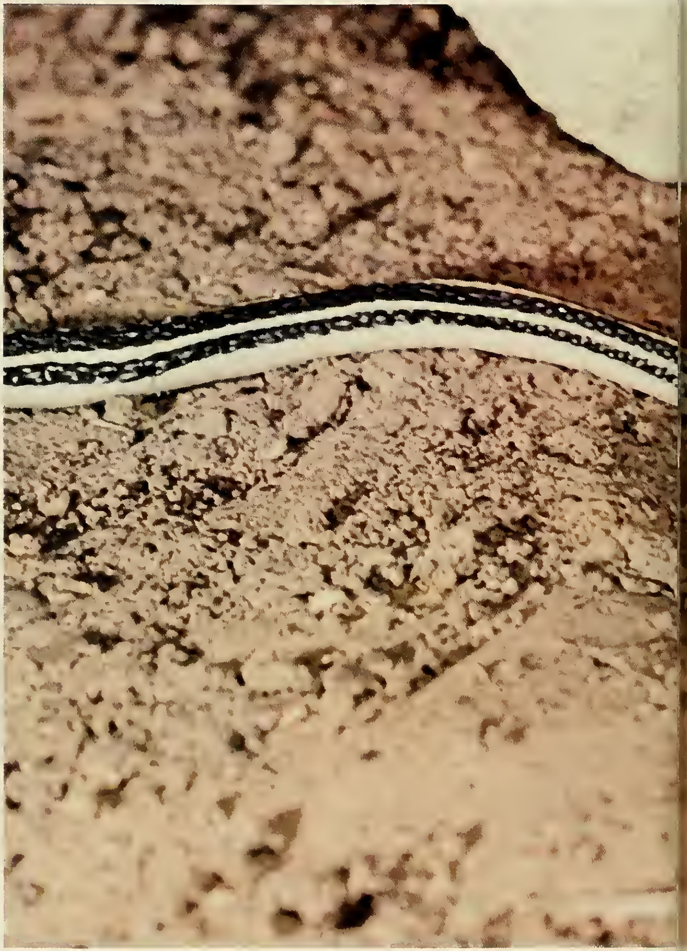
and thicker silk from her spinnerets onto the walls of the bag, and the following morning she hulked menacingly over the top of the completed egg case. But she still tolerated the toads, even when they squatted around the egg case or bumped it while pursuing termites and ants. I began to consider the possibility that the toads' ant-eating activities effectively reduced the numbers of this predatory insect in and around the burrow and thus provided a degree of protection for the egg case now and the baby tarantulas later.

Throughout the incubation period, the female tarantula periodically moved her egg case out to the warmth of sunlight streaming through a window and into the terrarium. Several hours later she hooked her fangs into a groove in the surface of the egg case and laboriously dragged it back into her burrow.

August 7. Hundreds of baby tarantulas poured from several small holes in the egg case. Most had already molted, changing in the process from all white to gray with a dark spot decorating their abdomens. Anxiously, I watched the toads hopping through the fuzzy carpet of tender young tarantulas clinging to the collapsed egg case and covering the back of the burrow. The toads appeared to take no interest in the tarantulas, which were approximately the same size as termites; I did not observe a single toad either stalking or eating a baby tarantula.

Thinking that even if the toads were not so crude as to immediately annihilate their protector's offspring and that they might accidentally ingest a baby in some kind of feeding frenzy, I dropped several dozen termites among the tarantula babies. One toad leaped into the writhing mass of termites and its stubby tongue punched out and claimed a soldier termite. Then others crept past baby tarantulas and stalked the rapidly dispersing termites. One large female toad had pushed her snout against a sluggish termite, when a baby tarantula suddenly scooted past the targeted termite and immediately found itself glued to a tongue and headed into the toad's mouth. But almost as quickly and much more forcefully, the toad shook the tarantula from her mouth—and I suspected why.

A microscopic check of scrapings from the abdomen of a baby tarantula revealed thousands of barbed hairs: the same hairs that serve adult tarantulas



*The snake is about to lunge at the toad huddled under the hulk of the tarantula. The snake is also about to meet the tarantula's fangs. The toad will soon be busily pursuing ants again.*

Kent Benedict

so well in repelling enemies apparently make youngsters unpalatable to the narrow-mouthed toads.

In the following weeks, the baby tarantulas dispersed throughout the terrarium, and once again Ammonita was alone in her burrow except for the toads. To test their loyalty and Ammonita's territoriality, I placed a half-grown female tarantula into the terrarium. The new resident excavated her burrow beneath a piece of shale. Before construction of this burrow, there had been an accessible space under the shale but the narrow-mouthed toads had rejected it as a home site. Now, however, two toads abandoned Ammonita and moved in with the young female who proved to be an excellent protector: each time an introduced snake poked its snout into her burrow, she forcefully evicted the trespasser. She began venturing farther and farther from her burrow during evening forays, and it was certain that soon she would meet Ammonita and a deadly struggle would result.

I knew the unequal contest had been fought when one fall morning I peered under the shale and found it vacant. Deep within the inner sanctum of her burrow, Ammonita stood over all that remained of her rival: several fragments of legs, a shredded cephalothorax, and two glistening fangs. Scattered around the chaotic pile of tarantula parts and snapping up ants that had been attracted to the carnage were all six narrow-mouthed toads.

As one male toad ducked under Ammonita and she touched him with a foot, I marveled at the interaction between these two dissimilar creatures. In its association with tarantulas, the narrow-mouthed toad has evolved an effective defense against the pressures of predation. The tarantula's fierce defensive behavior excludes most of those predators of a size dangerous to the diminutive toad, and the microhabitat of the burrow and overlying rock attracts small insects, providing a ready source of prey for the narrow-mouthed toads. And, with their appetite for ants, several toads per burrow can control these voracious invaders, which might otherwise harass adult tarantulas and consume eggs and spiderlings. The relationship between narrow-mouthed toads and tarantulas merits further study in all parts of their common Kansas, Missouri, Arkansas, Oklahoma, and Texas ranges. ☐

# Downtown Deer

*It's hard for a predator to snatch a mule deer on someone's front porch*

**by Valerius Geist**

Just north of Glacier National Park, hard by the border of the United States and Canada, lies Waterton, Alberta, a small settlement dating back to the days when the surrounding land served as a game sanctuary. In 1932, the area was designated the Waterton-Glacier International Peace Park to commemorate the many decades of good neighborliness enjoyed by the two countries. The Waterton of today, like other resort towns in the Canadian Rockies, follows the rhythm of the seasons. In summer it is alive with the hustle and bustle of visitors, and motels, cafes, and service stations do a thriving business. In winter, silence descends, many buildings are boarded up, the golf course is deserted, the big, castlelike hotel on the hill overlooking the valley is empty of humans, and most roads are barricaded. The town is hibernating until the next summer. All this is little call to distinction since all resort towns have a cyclic life, but a visit to Waterton, preferably in fall, soon makes one aware of another element that gives the town a special character. Waterton is home not only to people but also to a population of mule deer.

On my first visit, years ago, I had barely entered the town when I saw a large mule deer buck resting on a porch. He ruminated contentedly and eyed the people on the street; only the tourists stopped. To the residents the deer are old hat. Beside the porch stood another buck, calmly performing—as is the way of mule deer—a marking ceremony. A few houses down the street, two other deer were grazing the lush, well-fertilized lawns. And so it went. In the back alleys the mud was marked with a mixture of deer and people tracks, and the campground's large lawns served as an evening and morning rendezvous for a big group of mule deer. Deer rested in front of the church and reluctantly made way for worshipers.

In the morning when schoolchildren were on the road and deer were most active, the happy state of coexistence was most evident. It was even rare for a youngster to make a snowball and heave it at a deer. Typically, the children did what children do, and the deer did what deer do, and when a big rutting buck passed children on one side of the road, none paid any attention to it. The citizens of Waterton had learned to live with deer. Some neophytes still struggled to plant gardens and grow some ornamental bushes, but the deer crossed any fence at will. A few homeowners hung strips of metal on some sacred little conifers they had planted, hoping that the deer would be spooked by the rattling tin. Indeed, when the bucks horned these little trees, the metal clanked loudly, adding to the din made by antlers breaking branches and stripping bark. I saw one indignant woman rush out and, with a broom, land a resounding whack across the big bottom of a large buck that was demolishing one of her trees. Slightly ruffled, the old fellow jumped off a few paces, shook his head, waited until the woman returned to her house, then resumed destroying her trees.

For as long as anyone can remember, deer have always been a part of Waterton. Every Sunday in winter, visitors come from the surrounding

*Mule deer wander calmly through the yards of people's houses in the town of Waterton, Alberta. Wind often blows the snow off lawns, making ample forage available during the winter months.*

Robert Peterson, Time

*Few ornamental conifers or shrubs of any kind escape the depredations of mule deer resident in Waterton. What plants are not eaten or trampled are often horned by the males, as the buck in the photo below is doing. Horning can be a means of communication between bucks and results in broken branches and stripped bark.*

Erwin A. and Peggy Bauer

towns to watch and feed the deer. Waterton's cats live insecure lives, constantly on the alert to avoid deer, for an unwary cat is quickly treed or chased into a house or woodpile by deer. From the deer's point of view, the town is an ideal place to be: coyotes and mountain lions, which readily kill deer elsewhere, do not enter the town; the lawns and shrubbery provide a seasonal, rich food source; and the houses and hedges not only grant shelter from the frequent high winds but also generate powerful vortexes that remove snow around houses, allowing deer access to green forage. While some people are a nuisance, disturbing the deer with their constant approaches to watch or photograph them, they are pests that the deer have long learned to tolerate.

Mule deer in Waterton have become extraordinarily tame and do not lose their tolerance, even in summer when they are dozens of miles away from human settlements. I have sat with mule deer bucks in their subalpine summer range or followed them step by step for miles, approaching to within feet to see more clearly what they feed on or to inspect the texture of their velvet antlers or the extent and nature of wounds they have incurred.

All this is in sharp contrast to the behavior of the closely related white-tailed deer. While I have often followed some fifteen to fifty paces to the rear of a mule deer buck for the better part of a day to study its behavior, I found only one white-tailed buck that did not object. Even following that buck was not very fruitful since other white-tailed deer spooked at our approach. White-tailed deer are common in the park but they remain shy. I saw them mainly at dawn and dusk or when I came upon them accidentally in cover. In some sanctuaries, white-tailed deer do learn to tolerate people, but I have never seen them acquire the mule deer's degree of tolerance. Why do two anatomically similar deer species, related so closely that they produce viable, albeit sterile, hybrids, act so consistently different?

Both mule and white-tailed deer are rather primitive New World deer, a branch of the family that has evolved in North America for some thirty to forty million years. New World deer have primitive dentition and feet. Compared with Old World deer, they have lower-crowned cheek teeth and larger phalange bones in their legs. They are adapted for movement over soft ground or uneven terrain; the extreme adaptation of this type is found in caribou, whose hoofs are modified for traveling on snow crusts and bogs, as well as for climbing on rocky ridges and talus slopes. As in other lineages of mammals, deer in warmer latitudes are more primitive than forms adapted to tundra, taiga, and periglacial regions. The whitetail was originally subtropical, with a preferred habitat of patchy dense bush and wet plain covered with tall grass. It has radiated widely and now occupies a variety of habitats. The mule deer is a recent offshoot of the same genus, but adapted to slopes, rocks, deserts, and mountains.

In comparison with mule deer behavior, white-tailed deer appear not only consistently more "nervous" but also far more expressive in their communication. The two species have an almost identical repertoire of social signals, quite different from those of Old World deer, but the difference in expressiveness is noticeable in all social communication, from simple to complex acts. For instance, both mule and white-tailed deer extend a courtesy to conspecifics when grazing in a

*The residents of Waterton have become blasé about the presence of mule deer in their town. Some gardeners still object to the deer's eating habits, but even a whack with a broom will not discourage a buck from making a meal of a bush.*

group. When passing another, however, a mule deer tends to lower its head; a whitetail not only lowers its head but also extends its nose and crouches noticeably. In full submissive behavior, a mule deer doe crouches slightly, spreads her legs, pinches in her tail, depresses her back, and keeps her head high; a white-tailed doe, in contrast, lowers herself almost completely to the ground, extends head and neck, and moves off through the grass.

Nowhere is the difference in expression better seen than in the sparring matches of bucks, a ritual highly developed in both species. Sparring matches occur only between bucks of different dominance rank, that is, between individuals whose rank disputes have already been settled. In mule deer, the larger buck solicits sparring matches by approaching a subordinate, but no match begins until the subordinate responds (except between two bucks who have a long sparring relationship). When soliciting, a dominant approaches in a weak dominance display, intercepts and tilts its antlers in front of the subordinate. If it accepts the gesture of the dominant, the subordinate moves forward, engages antlers, and begins the match. The subordinate also breaks the contact by jumping back. At this moment both bucks look up and avert their eyes from each other for a few seconds. Often the smaller buck will then tilt its antlers toward the dominant, which responds and another bout of sparring ensues. These matches can last in excess of half an hour and are different from the rare dominance fights between bucks of equal size and status. Sparring matches have a distinct sporting flavor and do not lead to settling of rank; dominance fights, by contrast, are dangerous combat in which contested ranks are resolved.

The sparring matches of white-tailed deer contain the same elements, but their execution differs. In response to the soliciting dominant, a subordinate white-tailed buck crawls on its belly to the dominant, licks its face, and then slowly rises and engages with its antlers. The smaller buck may also evade the larger by crawling on its belly toward the rear of the larger male and looking up at him in the process. He may also repeatedly sniff the tarsal scent glands of the larger buck.

The responses of female mule and white-tailed deer to courting bucks also show interesting contrasts. Females of both species move off when a buck attempts to court them. The mule deer female trots forward and circles back, with her head held low; her circle forms a diameter of some five to ten paces across, thirty to fifty paces if she is hard pressed by the buck. The female white-tailed deer also circles. Head low, she bolts from the buck and gallops off in a circle some two hundred to four hundred paces in diameter.

Mule deer are relatively inexpressive in their behavioral signals. At times, however, they act as if they had to overcome a high resistance in other mule deer in order to be noticed. Compared with the whitetail, the mule deer is more conspicuously colored, noisier, and smellier. When bucks horn shrubbery they do so loudly and usually for long durations; in fact, they use horning as an orientation signal. When

Robert Peterson, Time

*Visitors from other towns are not blasé about the "downtown deer." They flock to Waterton in winter to watch and feed the deer. Caution should be used in feeding the animals, for a deer expecting a handout may strike out with a hoof.*

two large bucks are out of sight of each other, each listens in the direction of the other's horning. They then move to meet each other. To advertise their dominance, big bucks urinate on their tarsal glands, special glands on the inside of their hocks; the larger the buck, the more it urinates on its hocks and rubs them together. The hind legs of a rutting mule deer buck tend to be matted with urine; those of a white-tailed buck are less soiled.

For effective communication, a message may have to be repeated a number of times. In addition to such repetition, an exaggeration of the message may be necessary to crash through the resistances of the intended audience. Mule deer social behaviors are also often punctuated by "crashing through" signals, akin to what physiologists call rebound. (A nerve cell, held back from firing, will respond excessively, or rebound, when released from inhibition.) The courtship behavior of mule deer illustrates these methods of communication. Normally, the buck, his head held low, approaches a doe from the rear, calls softly, and averts his eyes. His facial markings closely resemble those of a newborn fawn, and his courtship call is similar to a fawn's suppressed distress call. In essence, he plays "baby" to get close to the female and to make her urinate. Once she urinates, the buck tests the urine to ascertain her state of estrus.

A doe does not always urinate in response to this type of courtship. Urine is her sole means of stopping and getting rid of an excessively eager buck, so wasting the liquid would not be in her interest. When the "baby courtship" fails, the buck takes a different tack. He stiffens and his nose begins to twitch; he emits a long, thin moan, and females around him become noticeably tense. With a roar, he pounces at the courted female, slaps the ground with his hoofs, and gallops off after the departing female, roaring with each bound and slapping the ground. The chase may go on for a quarter of a mile. Suddenly the buck stops, the female stops—and urinates. During this "rush courtship," a big buck acts as if all inhibitions have been shed, and he becomes a roaring fury.

A white-tailed buck, by comparison, does not exhibit the baby courtship. He normally approaches a female with a weak rush courtship, slaps the ground once or twice, coughs a few times, then gallops silently after the female. The precopulatory courtship of the white-tailed buck is brief compared with that of the mule deer and copulation is a quick affair. In mule deer, the male initiates copulation with a series of mounts, usually six to ten, but sometimes in excess of forty. In whitetails, such precopulatory mounts are rare. After copulation, female mule deer show abdominal contractions, which can continue for up to an hour. Such contractions quickly cease or are absent in the white-tailed doe. Also, judging from the fights that I witnessed, those of mule deer bucks are more furious than those of white-tailed bucks.

All this illustrates that mule deer have a calm disposition which is shattered only occasionally, permitting the animal to act excessively. This calmness pervades almost all of their biology. Mule deer probably manage their stock of energy more efficiently and live longer than the excitable whitetail. They have a slightly higher life expectancy and are slightly less fecund than whitetails. The reason why calm mule deer and nervous whitetails have evolved appears to lie in their predator escape strategies.

In social interactions where mule deer run after one another, such as during play or when a buck runs after a doe, they do so at a fast gallop, low over the ground. That is, they run like white-tailed deer. When mule deer are alarmed by a predator, however, they attempt to escape by bounding in peculiar, high-arching jumps, as if jumping on a pogo stick. This bounding gait sacrifices speed for height. Thus, rather than speeding up when escaping a predator, a mule deer slows down.

The whitetail often responds to danger by hiding in cover and remaining tense and motionless. This behavior would not be adaptive unless coupled with a quick getaway when the deer is detected by a predator. The whitetail's getaway is signaled by an explosive motion, like the outburst of a covey of flushed partridges. Then the whitetail gains speed in an attempt to put as great a distance between itself and the pursuer as possible. The escaping whitetail uses every means at its disposal to maximize speed, such as avoiding obstacles by running along familiar trails, following the fresh trails of other deer, and running downhill. It confuses pursuers by running into water or by crossing the trails of other deer, leading the predator on a rally run. The hiding and lightning-fast

*Sharing an area with humans seems related to the mule deer's predator escape behavior. A "calmness," as the author calls it, marks the species' response to an approaching predator. The calm is reflected in other behaviors of the deer and may account for their tameness. In contrast, the more "nervous" whitetails do not enter Waterton.*

Erwin A. and Peggy Bauer

*In the intense courtship of mule deer, below, a buck harasses a doe to get her to urinate. By testing her urine, he can determine her state of estrus. Sparring matches between bucks, right, are held between a dominant and a subordinate and do not affect status. Dominance fights between deer of equal size can be fierce and dangerous.*

escape are hallmarks of an excitable, nervous animal.

When trying to escape from a predator, a mule deer does not avoid obstacles; on the contrary, it heads for obstacles, in particular, steep slopes. With its high-arching bounds, it can easily clear obstacles and can do so in a zigzag fashion. A mule deer can bound rapidly uphill, imposing a prohibitive energy cost on a pursuer attempting to follow at equal speed. The bounding appears to have a function beyond that of permitting rapid uphill ascent or clearing of obstacles: it also allows a closely pursued deer to move in an unpredictable direction. That is, as the predator lunges at the deer, the deer accelerates upward and lands on a spot that cannot be predicted. Such evasive tactics are successful only if a targeted prey jumps out of the predator's reach at the very last possible moment. If the prey jumps too soon, the predator can reorient; if it jumps too late, it is killed. A calm, unexcitable individual is better equipped to judge when to jump. Thus calm, unexcitable mule deer appear to be a product of one of their predator escape strategies.

Classical ecological theory has made biologists look at differences in food habits of coexisting species. This approach has not been very successful, however, in explaining ecological differences between mule and white-tailed deer since their food habits are quite similar. What escaped the biologists' attention was that security is of prime importance to an animal faced by many predators. Thus, focusing on antipredator strategies and the tactical requirements that make them successful has made me see a landscape inhabited by mule deer and whitetails differently from how I had seen it before. Not food, but the tactical requirements maximizing security appear to be the best predictors of the whereabouts of mule and white-tailed deer.

The success of mule deer today may be an artifact of modern times, in particular the absence or scarcity of efficient predators. Their tameness, however, and their willingness to share with people the same general residential areas, particularly in national parks, seems an accidental consequence of their ways of escaping predators. We can enjoy them there, but it does not pay to get too close. Some will come for handouts and strike with a sharp front hoof if they fail to receive the expected cookie. ☐

# The High Importance of the Lowly Krill

*This small crustacean, crucial to the antarctic food chain, is threatened with possible overharvesting by humans*

### by Mary A. McWhinnie and Charlene J. Denys

Until very recently, Antarctica was most familiar as the great white continent surrounding the South Pole, populated primarily by seals and those delightful members of the avian world, the penguins. To anyone interested in ecology, Antarctica is also the area where fur seals were hunted to near extinction. But a ban on sealing has allowed them to recover. The ocean encircling the continent is, in addition, familiar as the scene of the demise of great numbers of baleen whales during the whaling industry's heyday.

Now, world attention has turned to a much smaller antarctic creature, the shrimplike crustacean *Euphausia superba*, commonly called krill. It is one of about eighty-six species of euphausiids, which are found in all of the world's oceans, but it is the only species properly called krill and the only one that has generated much scientific and economic interest. Although krill are relatively small—an adult animal may reach a maximum length of about 2.36 inches—their role in the antarctic ecosystem is pivotal. Krill are a primary food source for almost all higher species in the Antarctic—baleen whales, seals, penguins and other birds, fish, and squid. In fact, the yearly southerly migration of baleen whales to these waters to feed on krill during the austral summer was what made the Antarctic Ocean such a profitable hunting ground for whalers. The food reserves built up by the whales during their summer krill-feast sustained them to a great extent throughout most of the rest of the year in more northern waters.

Krill have a remarkably high protein content, approximately 50 to 60 percent of their dry weight. Their nutritional value compares favorably with other seafood and soybean products. This attribute, combined with the search for new high-protein food sources for human consumption, accounts, in the main, for a new interest in krill. Another factor is the decline in the number of baleen whales. Estimates of baleen whale populations suggest that from the early 1900s to the present there has been about a 65 percent decrease in their numbers. Thus, whatever those whales used to consume might now be available to a different consumer species—humans.

One aspect of krill biology that makes them particularly attractive as the object of a new fishing industry is their habit of congregating in large, dense aggregations, sometimes referred to as swarms. These are occasionally sighted at the surface of the ocean as large, reddish patches. The largest recorded swarm measured about 2,000 feet in diameter, but most swarms average from 125 to 200 feet in diameter and are found anywhere in the upper 650 feet of water. In the austral summer of 1975–76, the West German trawler *Weser* averaged eight to twelve tons of krill per hour of net towing, with a maximum catch of thirty-five tons in eight minutes. The potential for a new industry is clear.

From a scientific and conservation point of view, however, things are not so clear. Of primary concern is that any new fishery not damage the antarctic ecosystem. With the ravages caused by unrestrained whaling still foremost in world consciousness, particular care is being taken to estimate what quantity of krill might be safely harvested. This reflects not only concern for safety in terms of the maintenance of the krill population itself but also safety in terms of the survival of the numerous species of animals that depend wholly or primarily on krill as their food source. The relative simplicity of the antarctic food chain makes it particularly vulnerable to disturbance and irreparable damage.

As the numbers of baleen whales decreased over the years, the potential krill surplus probably became a food source for growing populations of other animal species. Crabeater seals, which inhabit antarctic waters and feed primarily on krill, are known to be increasing in number. Consequently, there may be no actual surplus for human harvesting. Humans, instead,

Peter Johnson

Peter Johnson

might be competing for food directly with the seals or with penguins and other krill-eating animals. This competition would not necessarily entail damage to other species, but might reduce their numbers to previous levels.

All estimates of the quantities of krill that can be safely harvested and the potential impact of the harvesting on the antarctic ecosystem are, however, severely hampered by a lack of detailed information on overall krill biology. The need for information has become critical in the face of ongoing small-scale fishing tests in antarctic waters to determine the feasibility of full-scale krill-fishing operations there.

The original studies of the biology of krill were done during the British *Discovery* expeditions of the 1920s and 1930s. Nearly all the classical information on krill is contained in a voluminous 400-page work by J.W.S. Marr, who was part of those expeditions and investigated countless preserved samples of krill. Marr laid down the framework for all future research on this species. His conclusions, published in 1962, some thirty to forty years after the expeditions, remained essentially unchallenged until a system was developed in the mid-1970s for maintaining krill alive in a laboratory.

This development opened a new door in krill research by permitting captive animals to be studied over long periods of time. The system itself is quite simple, requiring only large tanks provided with flow-through seawater, maintained at temperatures below 39°F. Previous attempts to maintain krill alive in individual containers proved relatively unsuccessful for long-term maintenance. Part of the problem may have been lack of moving water to promote filter feeding and lack of temperature control.

That krill are found only in the Antarctic reflects their extreme sensitivity to what is for them elevated temperatures. The Antarctic Ocean is defined hydrographically by a moving boundary previously called the Antarctic Convergence but now known as the Polar Front. Of prime importance in krill distribution is the temperature discontinuity associated with it: south of this boundary temperatures remain below approximately 43°F, and north of it temperatures are considerably higher. Krill are superbly adapted to their frigid, watery environment, maintaining constant and often rapid

movement at temperatures in which investigators' hands are quickly paralyzed by the cold. The price for this adaptation is an inability to withstand any significant rise in their environmental temperature.

A sizable portion of the early work on krill was devoted to trying to determine how fast they grow and how long they live. Nowadays, these questions have become of utmost practical importance because life span is directly related to a population's ability to maintain itself in the face of harvesting. The longer it takes an animal to mature, the less resilient is the population.

Original estimates of krill life span were devised by examining formaldehyde-preserved samples and noting how many animals there were of any particular length. Using this method, most (but not all) of the animals were found to be approximately one of two sizes. An assumption was made that each peak size represented animals that were hatched within a given year, and the conclusion was drawn that the smaller group was a year old, and the larger group two years old. Consequently, the life span was estimated to be a bit over two years.

The assumption, of course, is that as animals get older, they get larger. It is true that as a crustacean grows, it must molt to replace its exoskeleton with a larger version since its rigidity will not accommodate an increase in body size. So, generally, a crustacean such as the lobster molts as it gets older and larger.

But krill have a peculiar biological quirk—for them, molting is not neces-

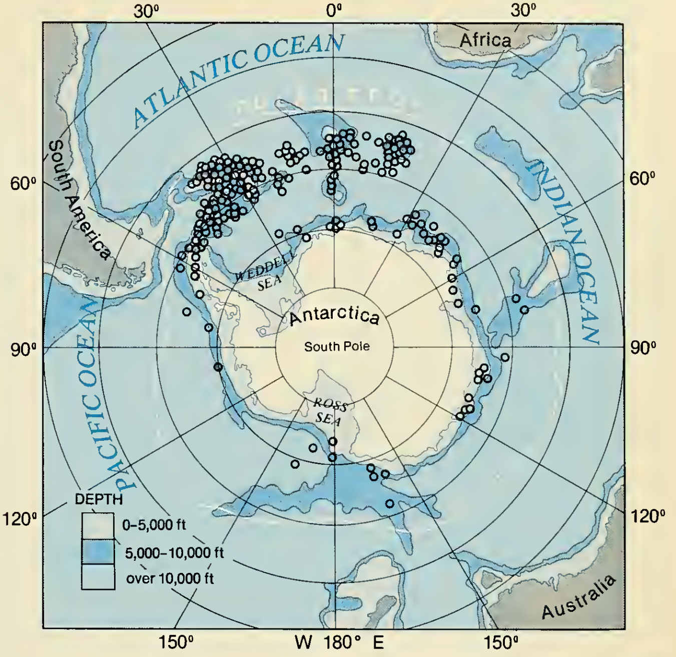
Distribution of Antarctic Krill



Joe Lemonnier

sarily tied to growth. Instead, for unknown reasons, molting occurs at approximately constant intervals, whether or not the animal has increased in body size. Because of the patchy distribution of phytoplankton—the minute plant organisms that make up the major food source for krill—and extreme seasonal changes in light essential for the photosynthesis of these plants, krill cannot be assured of a steady food supply. Occasionally, specimens with empty digestive tracts are caught. Since live krill are almost transparent, it is easy to determine whether they have eaten. (A well-fed krill has a visibly green stomach, liver, and intestine; the color is faint or absent in nonfeeding animals.)

For survival, krill must swim throughout their lives; there is no rest, ever. Resting causes them to sink, taking them down to ocean depths where phytoplankton are absent because of inadequate light for photosynthesis. For krill to swim efficiently, good muscle attachments to the exoskeleton are a must. In times of inadequate food supply, krill can actually molt themselves down to a smaller size and maintain swimming efficiency. A population of krill kept in flow-through seawater tanks over the winter (at which time the phytoplankton content of the water is very low) showed a dramatic overall decrease in length. If their age had been ascertained solely on the basis of size, it would have been grossly underestimated.

Other attempts at establishing age have been based on the state of sexual maturity, determined both from the internal state of the gonads (the reproductive organs) and from secondary external sex characteristics. The adult female has a cuplike structure, known as the thelycum, on the ventral surface into which the male places two baseball-bat-shaped packets of sperm called spermatophores. Once placed on the female, the sperm packets extrude the sperm into a chamber of the thelycum, where they remain until the female is fully mature and releases her eggs. At that time, the female rocks the thelycum back and forth, forcing the sperm out of a slit that the eggs must pass. Fertilization is external. In the process of passing by the slit, the eggs are fertilized and released into the water. Depending on her size, a female may spawn 2,000 to 5,000 eggs over a period of a few hours, but because of natural mortality and predation, very few of these progeny live to become mature breeding adults.

Much effort has been put into observing the stages of development of the thelycum as a clue to the rate of maturation. The external sex characteristics of many crustaceans, such as crayfish, pill bugs, and sand fleas, are known to regress to less mature-appearing states after the reproductive season is over. Krill have the same rejuvenation strategy. Far from dying after spawning, as had previously been supposed, the female molts, thereby ridding herself of the sperm packets that externally identify her as having been mature. Within a short time, the ovary reorganizes to a seemingly juvenile state, with no mature eggs. And so, the maneuver is complete. With no ready clues to a previous spawn, no one could guess that many supposedly immature females found in samples had already spawned.

How often female krill go through this rejuvenation cycle is unknown. So far there is clear evidence for one such cycle; there may be more. Needless to say, this state of affairs does nothing to clarify how long they live, but together with evidence of their potential for shrinking, it puts Marr's estimate of a two-year life cycle into question. More likely, females live three or four years, perhaps more, and males probably have a similar life span.

While krill were spawning in the laboratory, the temptation to try to rear them from eggs was irresistible. With a diameter of 0.039 inch, krill eggs can conveniently be photographed during cell divisions, the first rudimentary appearance of limbs, and finally, the hatching of the first of twelve larval stages, the nauplius.

This initial oval larval form bears no resemblance to the krill's later adult form: it does not feed (its digestive

*The bones of a baleen whale litter a beach on King George Island, off Palmer Peninsula in Antarctica. These whales, known to migrate to the Antarctic to consume krill, became the easy prey of whalers. Overharvesting is estimated to have reduced their population by about 65 percent in this century alone.*

How to buy value in art.

"Greasborough Dusk," an original lithograph by George Guest. At $130 it typifies the very remarkable value that Christie's Print Collection offers in original etchings, lithographs, linocuts, etc. Attractive landscapes and figurative works by rising young artists from around $100 to $150. And of course the works of such masters as Chagall, Miro, Moore.

Each work is an authentic original, numbered and signed by the artist. Then it is stamped with Christie's seal of authentication and delivered to your home.

Let us send you our free colour portfolio and price list. There's no better place to buy original prints. There's no better time than now.

tract is not yet complete and won't be until it reaches the fourth larval stage), its swimming capacity is quite limited, and it has only three pairs of appendages compared with an adult's nineteen pairs. The first two pairs eventually alter in structure and function and become the antennae and antennules of the adult, and the third pair gradually transforms into one of the adult mouthparts, the mandibles. In terms of evolution, crustacean mouthparts are modifications of legs. These transformations can be observed through the many larval stages of krill development.

Laboratory rearing was successful only to the third stage, the metanauplius, after which the animals succumbed to an invasion of bacteria, a common problem in rearing planktonic species in captivity. Previous investigators, working with preserved samples caught at various times of the year, have inferred that a larva takes about nine months to pass through all twelve stages and become a miniature krill, at that time only about one-quarter to one-half inch in length. Reliable information on the krill's first year of life still awaits the laboratory rearing of larvae through all stages.

Often, samples of krill fished from the ocean are predominantly of a single age—larvae, adolescents, or adults. With about 24 million square miles of Antarctic Ocean to inhabit, how do aggregations occur at all, let alone age-specific ones? Clearly, this propensity for distribution in dense patches is what makes krill a good food source for animals and potentially a good fishery resource. If krill of all ages were evenly distributed throughout the vast expanse of ocean, feeding on them would be inefficient and fishing for them impractical. Since swarms do not appear to be uniform mixtures of all ages, perhaps an understanding of how krill form and maintain swarms, and how the swarms themselves behave, might allow for selective fishing; for instance, swarms of mature animals could be avoided during peak reproductive periods.

True swarms, which can be at varying depths, are similar to fish schools in that the animals are oriented parallel to one another and the swarm appears to move as one large, integrated organism. Some krill aggregations are not so highly organized but apparently remain together. This togetherness is maintained both horizontally and vertically, as the krill tend to move closer to the surface at night and to greater depths during the day, apparently in response to changing light levels. How do they accomplish the feat of remaining together?

One likely mechanism is light signals among the krill themselves. At night, the ocean is sometimes filled with tiny, blue green lights that scintillate brightly like a fairyland creation. Many organisms contribute to this magnificent luminescent display; foremost among them are the krill. Each animal is equipped with ten round, cuplike light-producing organs called photophores, which the animal can flash on and off or keep brightly lit for some minutes.

The chemical production of light by organisms ranging from molds to fish has fascinated people, probably for millenniums, but its function in many species is still poorly understood. A clue to its function in krill may be the observation that krill are attracted to dim light. In laboratory experiments, their attraction to light of different wavelengths (colors to us) was tested by shining a narrow beam of light into a large tank and then taking flash photographs of the krill distribution. The animals were found to aggregate in this light even though it was too dim for the human observer to see. Perhaps by producing light of their own, krill are attracted to each other, forming and maintaining aggregations.

Their large and prominent black eyes are well adapted to life in relatively dim light—a study of their optical properties has shown their eyes to be sixteen times more sensitive to light than are ours. In fact, when taking the laboratory photographs, it became evident that krill were still responding by aggregation to light intensities too faint for us to see.

In this faintly lit environment one also wonders what means mature males and females use to recognize each other for mating. The answer may be pheromones (chemical secretions) or some visual cue, for example, sex-specific bioluminescent flash patterns. Mating has never been observed, however, so theories about recognition are still purely conjectural.

On one occasion, the peculiar behavior of two krill in the tanks suggested that mating was occurring. The two animals were hastily removed and examined, and much to our surprise, the head of one was missing. There hadn't been any mating; it was cannibalism that was going on. The color of the predator krill's gut confirmed that it was making a meal of its peer; instead of the usual phytoplankton green, the intestine contained black eye material and the liver was reddish from the carotenoid pigments of the prey animal's chromatophores—pigment-containing cells.

Casual observation of the tanks subsequently showed a low but steady incidence of cannibalism. The question that arises is, was this a natural, normal occurrence or an artifact caused by captivity? We found that even in natural populations, some cannibalism occurs and not necessarily in response to low food levels. Among many well-fed krill caught at sea, we would occasionally find one with the telltale red gut.

In fact, the krill appears to be an opportunistic omnivore, rather than an exclusive herbivore, as previously thought. Krill have been found eating pteropods (small snails with a foot modified into a winglike structure with which they "fly" through the water, giving them the name "sea butterfly"), copepods, annelids, detritus, and even chips of paint that have inadvertently entered the holding tanks on board ship. The constant filtering movements the krill make with their finely bristled thoracic legs are probably not as selective as once thought. This makes good survival sense since an omnivorous feeding habit is more flexible than a selective one. To what degree this flexibility affects the growth (or shrinking) rate of krill in low phytoplankton conditions belongs again to the long list of questions on their biology.

As these many studies on krill biology are proceeding, so are the commercial fishing tests and product development both in the United States and abroad. The Japanese and Russians were the pioneers in krill processing as well as harvesting. In both Japan and the USSR, krill products have been available for human consumption for some years as cooked frozen whole krill, pastes, and spreads. Chile has developed a process for producing "krill sticks" similar to the familiar fish sticks in our supermarkets. Krill has reached the U.S. marketplace primarily as food for pet fish. Krill are also used, but not yet in the United States, as a protein filler in any of a number of products—sausages, sauces, soups, meatballs, pies, and stews. Because it has only a faint taste, krill meat, like soybean meal, is an excellent high-protein extender for a wide variety of food products. Beyond its potential as a human food source, krill meat may some day find uses in domestic animal feed and in aquaculture where the red pigments of the krill impart a commercially desirable pink color to the flesh of fish fed on them.

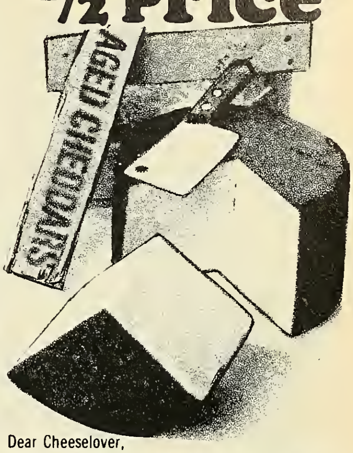
The development of new krill products does not stop with the meat, however. The chitin, or horny portion, of the exoskeleton can be purified into a substance called chitosan that has potential application in such diverse fields as water purification, chromatography, pharmaceuticals, food stabilizers, paper manufacturing, and adhesives. In fact, the adhesives used for gluing together the wooden airplanes of World War I were derivatives of chitin.

The raw materials for these products are derived from a present annual harvesting rate on the order of 80,000 to 90,000 metric tons of krill by the USSR, Japan, Poland, West Germany (FRG), Chile, Norway, Korea (REP), Argentina, and Spain. Such catch rates are relatively small when compared with estimates of standing stocks of krill ranging from 125 million to 6 billion metric tons.

These stock estimates reveal two important considerations: first, that the stock is indeed large and commercially attractive, and second, that there is as yet no reliable method of assessing its actual magnitude. Stock assessments made thus far have relied on scant data. Some estimates have been based on extrapolations of how large a krill population the phytoplankton of the Antarctic Ocean could support; others have relied on localized sampling of krill. Given the patchy distribution of both phytoplankton and krill, neither method is very reliable. The possibility of using satellite photographs of the Antarctic Ocean for the detection of large swarms of krill offers more promise but is still in its early stages of development.

The combination of accurate stock estimates and answers to basic biological questions concerning krill holds out the best promise of a harmonious combination of resource utilization and conservation. And the international recognition of the need for additional regulations reflects an awareness of the necessity for judicious management of Antarctica's unique resources and the preservation of its remarkable ecosystem for present and future human generations. ☐

CHEDDAR
1/2 Price



Dear Cheeselover,

This kind of Cheddar is almost extinct. Aged **slow**. Cured **sharp**. Bursting with flavor. It's **not** orange inside like ordinary cheddar. It's snow white—because **no** coloring, **no** chemicals, **no** preservatives are added. For **half price** I will ship you an entire virgin 2-lb wheel. Please eat as much as you like. If not the best Cheddar of your life, simply return what is left (toothmarks and all) and I will refund all your money (postage and all).

**Why this half price offer?**

I think you will love my Cheddar enough to order again—at full price. And then again after that. However, only a fraction of this curing will be released at half price. (May I suggest you use our toll-free number to avoid possible disappointment?).

Sincerely,
Gerard Paul
Gerard Paul

**If you make your Cheddar request before April 30, 1980, we will include (free) the CHEDDAR CLEAVER shown above. It is razor-sharp, half-a-foot-long, and regularly sells for $5.00.**

**CHEDDAR REQUEST**

**MAIL TO:** Cheeselovers, Dept. 569-3
Box 1200, Westbury, N.Y. 11590

Dear Mr. Paul—Please ship your 2-lb. wheel of sharp-aged farm Cheddar for half price—only 7.49 (reg. $15.00). I am free to eat as much as I wish. If not the best Cheddar of my life, I may return what is left for a full refund (including postage). (C51292)

*Roaches who ride the city's buses now have a foe in the Museum*

Dear Sir,

I'm hoping this is not another exercise in futility. Letters of complaint are so easy to ignore, so I rarely, if ever, write them. It seems only the danger of public exposure produces any effect.

Most of the time, despite momentary flashes of anger, one can shrug off the indifference, hostility, and even outrageous rudeness unleashed by bus operators on the unfortunate riders of the New York City bus system.

But Roaches!!! And from the many sizes, second generations of them!! How dare you inflict this on those who support your system, pay your salaries, and put their trust in you. Roaches—I will not sit still for them. This horde of roaches was on bus number 8553, October 4, 1979, at 2:50 P.M.

This obviously bespeaks gross negligence as well as total indifference. Littered buses, soiled windows—bad enough. But vermin? I can't imagine the heyday the media could have with such a news item, and unless something is done, and fast, I shall do everything in my power to see that it is publicized.

(Signed) A Disgusted Rider

Cockroaches have been riding the city's buses for over fifty years. Generally, they have kept a low profile and stayed out of trouble. In the last few years, however, the dramatic increase in the number of bus-riding roaches has driven some of their fellow commuters to the point where they have felt compelled to write to the New York City Transit Authority (witness the above letter). After trying one ineffectual remedy after another, the Transit Authority finally turned to the American Museum of Natural History last year for help.

Joseph DeVito, director of safety for the Transit Authority, explained the peculiar and paradoxical nature of the problem: "A few years ago, the T.A. embarked on a comprehensive program of bus washing. Believe it or not, the more we washed the buses, the more complaints we got about the roaches." In response to the rising tide of letters the Transit Authority stepped

*Roaches often take free rides on unsuspecting humans.* Paul Sher up its insect bomb and fumigation program. But the itinerant roaches, like roaches everywhere, held fast to their domain. Other remedies were attempted: one ingenious engineer even rigged up a grid of live wires in a favorite roach hangout on one bus, but after several electrocutions the bugs learned to avoid the trap.

It was at this point that Herb Crannan, a Transit Authority executive, suggested that an entomologist might be able to help. Explains DeVito, "We hoped that by studying their behavior, perhaps there would be a way—something like the Pied Piper of Hamelin—to get the insects to march right off."

Betty Faber, a research associate in the Museum's Department of Animal Behavior and an authority on roach behavior, offered her expertise free of charge. The T.A. gave her a transit pass, and she began riding the buses and visiting the terminals, jotting down the behavior of the itinerant roach in her field notebook.

Faber is used to following the vagaries of roaches; she keeps her own colony of wild roaches in the Museum's rooftop greenhouse, where they share quarters with electric eels, black-jawed fish, and various aquatic and terrestrial plants. Faber provides her roaches with protection from insecticides, but the roaches have to shift for themselves when it comes to food and water. Each roach, in turn, assists her in her research by wearing a numbered tape strip on its back. At night, bathed in the glow from an infrared light invisible to roaches, Faber can be found stalking her busy wards while they go about their business or watching them on closed circuit television from cameras set up in strategic locations.

The cockroach, Faber explained, is among the earth's most venerable inhabitants. It has survived because it has been able to cope with changing environments. Its eclectic eating habits may have helped: the roach has feasted on everything from brontosaurus flesh in reeking Cretaceous swamps to stray

If you'd like to know why Jack Daniel's tastes different, drop us a line.

IF THE SUPREME JUDGES of Jack Daniel's Whiskey don't agree, the minority rules.

These gentlemen taste our whiskey as it comes from room-high vats of tightly packed, hard maple charcoal. And even if only one taster says the charcoal needs changing, the vat is emptied and changed. What's more, the last batch of whiskey through is put through again. That way, we can be sure not even a minority of our friends will ever find fault with Jack Daniel's charcoal mellowed whiskey.

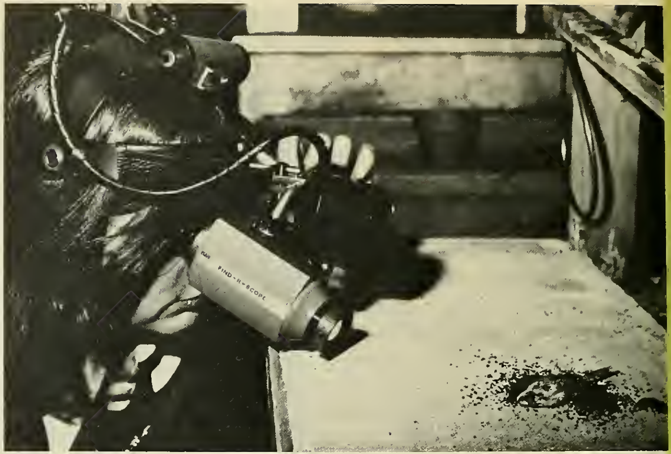
*Placed in the National Register of Historic Places by the United States Government.*

*Faber follows the nocturnal habits of her roaches with this special magnifying camera that can "see" in invisible infrared light.*



Paul She

crumbs in spotless Park Avenue kitchens. It even eats the inner organs of televisions sets and refrigerators.

The roach's adaptation to city life is quite remarkable. Despite vigorous efforts to eliminate them, roaches can be found at the best addresses and in some of the finest restaurants in New York. (Faber cited one exclusive restaurant that contacted her about a seemingly unsolvable roach problem.) And, of course, they are sometimes seen riding the city's buses.

The bus-riding bug, Faber says, is usually the German cockroach. Long a victim of wanderlust, this peripatetic roach immigrated to New York City at least a century ago and established itself as the dominant species. (The larger American roach is still around, however.) Like most cockroaches, the German roach is attracted to water. Faber suggested that the comprehensive bus-washing program may have made the city bus a wetter, and thus more appealing, environment. People eating on the buses provide the roaches with food (she noted that eating on buses is more common now than five years ago), while the engine and heating system provide them with warmth.

But the real question is how roaches get on the buses in the first place. "A roach," says Faber, "could conceivably climb on a bus while it is in the terminal. But the terminals, contrary to popular opinion, are very clean and most are unheated. Anyway, it's like climbing Mount Everest for a roach to get on a bus by itself." She also discounted the theory that roaches breed on the buses.

"I think it's safe to say that the roaches get on with the passengers and then get off the passengers while they are on the bus. These German roaches will hang on tight when disturbed or upset. A perfectly clean person could be carrying a roach this way."

When Faber files a report with the Transit Authority, she will recommend simply that the buses be kept clean and dry, especially the back-seat area, where roaches and rubbish tend to accumulate. This approach may prevent roaches from staying too long on any one bus, but it won't prevent them from getting on with people. That problem, many agree, is unsolvable. "There isn't that much you can do about roaches, after a point," says Faber, "except to learn to live with them. Roaches are a lesson in humility for all of us humans."

Or, as archy the cockroach, created by Don Marquis, put it:

i do not see why men
should be so proud
insects have the more
ancient lineage
according to the scientists
insects were insects
when man was only
a burbling whatisit

**Guarding the Source**

An important concern of anthropologists has been how to preserve source material of rapidly changing or dying cultures. L.P. Greenhill, founder of the U.S. Archives of Encyclopaedia Cinematographica, will present *Film as a Means of Safeguarding Source Material in Ethnology* on Sunday, March 9, at 2:00 P.M. in the Auditorium. During his discussion, he will show a number of German ethnographic films that are meant to be an objective record of human behavior for later anthropologists to study. Most of the films are presently stored at the Institute of Scientific Film in Göttingen, West Germany. There is no admission charge.

**Discovery Tours**

The Museum is offering a tour of Papua New Guinea and Australia this September. Museum ornithologist Mary LeCroy, a specialist on birds of paradise, and Australian anthropologist Keith Buxton will lead tour participants to the remote areas of the South Pacific in search of wildlife. Tour members will also observe the markets, villages, and ceremonies of the indigenous peoples of the area. The Museum is sponsoring other trips to the British Isles, Alaska, and China in 1980. For further information, write to Discovery Tours at the Museum.

**Microbes, Millipedes, and Mountain Lions**

The spring series of *Workshops for Young People* will begin in April. The weekend workshops provide an opportunity for children in grades 4 through 7 to learn about such topics as nature photography, the microscope, mammals of North America, human origins, and insects. The courses run from two to six weeks and cost between $10 and $20. Write to the Museum for more information.

**The Rising Sun**

Japan is the featured country in the People Center during March. On four weekends, the many facets of traditional and modern Japanese culture and society will be presented through lectures, films, demonstrations, music, and workshops. The programs, which will run from 1:00 to 4:30 P.M. on Saturdays and Sundays, are free and open to all Museum visitors.

**The Biggest of Them All**

On Sunday, March 16, at 2:00 P.M. in the Auditorium, Ismael Calderon, of the Department of Education, will use sound recordings and films to illustrate the environment, behavior, and ecology of whales. The show, *Whales*, is open only to members of the Museum and their guests.

A report on the great American forest.

# The all-purpose forest has something for everyone.

The forest is one of the most useful resources the planet has been blessed with, providing thousands of products that are not only convenient and pleasant but essential: lumber and building materials, paper products, packaging, chemicals, fuel.

But the surprising, bountiful forest is also a source of other enduring benefits:

Fishing streams, for example.

Nature trails.

Swimming holes.

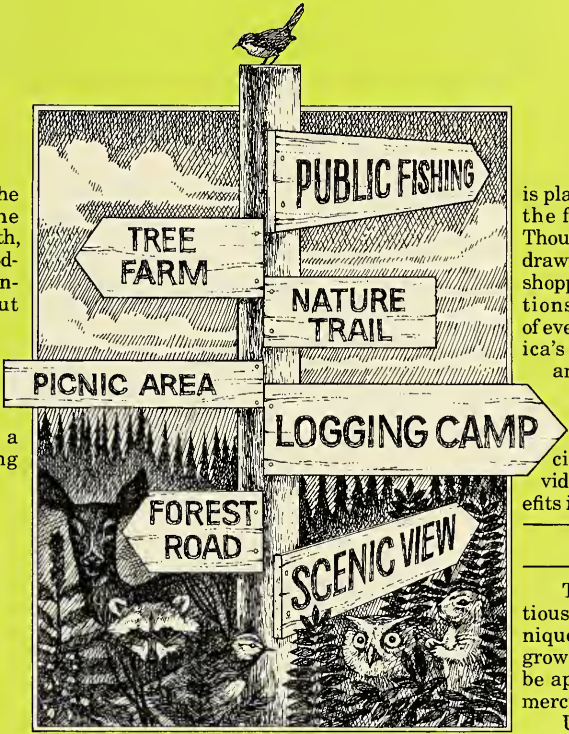
A place for Sunday drives.

Grazing land.

Board and room for wildlife.

Pure water.

And escape.



## Sharing the benefits

All these can and do coexist in the working commercial forests of America. (*Commercial forest,* as defined by the U.S. Forest Service, is *all* forestland — whether owned by individuals, government or the forest industry — that is capable of, and potentially available for, growing repeated crops of trees for harvest. It includes land in National Forests but not in National Parks or Wilderness areas.)

But demands on the commercial forest are growing at an alarming rate. An expanding population is placing new pressures on the forest for recreation. Thousands of acres are withdrawn every year for homes, shopping centers and additions to Wilderness. And of even more concern, America's consumption of wood and paper products is expected to double in the next 50 years.

Can the commercial forest keep on providing these multiple benefits indefinitely?

## The big if

There is reason for cautious optimism *if* the techniques used by industry to grow more trees, faster, can be applied on *all* our commercial forestland.

Unfortunately, trees are not growing fast enough in all commercial forests. Productivity is less on privately owned land than on industry's and is seriously lagging in National Forests.

So there is a long road ahead if America is to continue to receive multiple benefits from the forest.

If you'd like to be better informed on how important it is to keep America's forests productive, write American Forest Institute, P.O. Box 873, Springfield, VA 22150 for a free booklet, "The Great American Forest."

The great American forest. Trees for tomorrow. And tomorrow. And all the tomorrows after that.

**Trees. America's renewable resource.**

# Two Satellites in Search of X-rays

*Information from observatories orbiting in space bears on the question of whether the universe is open or closed*

The "diffuse background" of X-rays that bombard the earth equally from all directions in space has been studied with two recent NASA satellites, HEAO-1 and HEAO-2. The results indicate that the universe may be filled with superhot gas or with an unexpectedly large number of quasars or possibly with both.

The diffuse background was discovered in 1962. Ever since, astronomers have differed as to whether it is truly a diffused (that is, widely distributed rather than localized) emission or the result of innumerable individual objects, each of which produces X-rays. The problem reminds me of the ancient concept of the Milky Way as a luminous stream in the sky. Galileo's telescope later revealed that the stream was simply the summation of millions of faint stars that cannot be individually distinguished by the human eye. Is that the case as well with the diffuse background of X-rays? Are our first X-ray instruments just too crude to resolve a myriad of cosmic X-ray sources?

The diffuse background actually differs depending on the X-ray energy at which it is observed. Shorter-wavelength X-rays have higher energies and are called "hard" X-rays; "soft" X-rays are those with lower energy and longer wavelength. Measurements made since 1962 have shown that the background of the shorter-wavelength hard X-rays (those with wavelengths less than about 1/1000 of visible light) is isotropic, meaning equally bright in all directions as seen from the earth. This indicates that the radiation is not produced by stars (or by hot gas, for that matter) in our own Milky Way galaxy. If it were, it would be brighter in some directions than others. The observation of isotropy thus indicates that whatever produces the diffuse background of hard X-rays must be far outside the Milky Way, in remote extragalactic space.

Measurements of the background of the longer-wavelength soft X-rays, on the other hand, *do* show pronounced deviations from isotropy and indicate that the background is largely produced within our galaxy. That makes it difficult to observe the diffuse emission of soft X-rays from beyond our galaxy, although observations of bright "point" sources, such as distant quasars, are possible. This difficulty is germane to the story that will unfold below, and is analogous to the effect of a full moon in the sky, whose scattered glow in the atmosphere makes it hard for a viewer to see the Milky Way, although individual bright stars can still be readily perceived.

Each of the HEAO (High Energy Astronomy Observatory) satellites that observed the diffuse background carried several instruments to study X-rays from the cosmos. The payload of HEAO-1 included an instrument known as A2 that was designed to study the overall structure of the universe as it might be revealed by X-rays from distant space. HEAO-2, dubbed *Einstein* to commemorate the great physicist, carried a large telescope capable of focusing an X-ray image onto any of four onboard instruments, as chosen by command from the ground. With the aid of this telescope,

RMT Our team of botanical and wildlife experts has compiled a programme of tours that is both exciting and imaginative.

**BOTANY & WILDLIFE 1980**

**China** — the first botanical tours to China staying in Peking, Chengtu, Mt. Omei, Kunming and Hong Kong. Departures on May 4; May 11; May 18 and October 5 for 22 days.

**Kashmir** — flower hunting in beautiful mountain country with easy pony-riding or walking, botanising excursions and three idyllic days in houseboats at Srinagar. Tour leaves June 21 for 23 days with a stop-over in Delhi.

**Papua New Guinea** — the plant and bird life with ample time allowed at the Bensbach Wildlife Lodge, the Baiyer River Lodge and the Wau Ecology Lodge. Departure on August 9 for 26 days with a stop-over in Singapore.

**Australia** — the flora of tropical Queensland with visits to the Girraween and Lamington National Parks, the Atherton Tablelands and the Lake Barrine National Park. Leaving September 8 for 23 days with stop-overs in Singapore and Sydney.

Experts escorting the tours include Kenneth Beckett, Anthony Huxley, Roy Lancaster and Bryan Sage. Details of these and other tours from our New York representative:

This Winter We Toured The Galaxies With 200,000 People. Soon We're Going To Saturn, Halley's Comet, The Milky Way...

If you've been impressed all your fe with the stars that punch you the eye on a warm summer's night, ou should be reading ASTRONOMY nagazine. If you've thought you could ever appreciate the "music of the pheres" you ought to try ASTRONMY magazine. If the wonder and xcitement of a billion spears of ght seems just beyond your understanding, you should be subscribing o ASTRONOMY.

Month after month, with observaory-quality color photographs, lavish aintings and crystal clear writing, STRONOMY makes the adventure f space as exciting as today's news. Vhat was once dry-as-dust physics nd mathematics become transormed into easily understood exlanations of the wonders above us.

Today 200,000 readers have ntered the universe of ASTRONMY, the country's largest astronmy magazine. You'll find absorbing rticles about galaxies - red dwarfs - oscillations of the universe - Mars - red variables - photographic astronomy - Voyager missions - rings around the planets - climate changes - star swarms - black holes - and much more.

There are popular departments such as Equipment Atlas, which delves into astronomical "tools of the trade" for amateurs; Gazers Gazette, a short course in observing each month; Sky Almanac, your guide to the sky; Star Dome, to help you explore the skies in detail; Forum, controversial and intriguing; Astro-News for late-breaking items; Astro-mart for free classified ads; and a regular book review guide for further reading.

Astronomy has come of age. We've learned more about the vast spaces around us in the last 30 years than in all previous history. Young people today know more about galaxies, clusters, quasars, plusars and mysterious black holes than the expert astronomers of 50 years ago ever dreamed about.

Become a subscriber to ASTRONOMY and join us in our travels through the unfolding universe. In its pages you'll find new worlds of wonders piling in on one another as your knowledge and appreciation of the heavens grows greater each month.

Special Offer To Natural History Readers

If you send check or money order with your subscription, we'll add one bonus issue to your subscription - our "thank You" for helping reduce our paperwork.

the HEAO-2 instruments were employed to make the most sensitive observations yet possible of individual X-ray sources beyond the solar system, such as distant stars and galaxies.

HEAO-1 was launched in August 1977 and shortly thereafter the A2 experiment began mapping and measuring the diffuse background. A most important task was to measure the intensity of the background in hard X-rays as a function of the wavelength of the rays. The dependence of intensity on wavelength, which is demonstrated in the X-ray spectrum, gives clues to the physical process that produces observed X-rays. Further, if it should be true that the diffuse background arises in numerous individual sources, then the spectrum of the background should resemble the summation of the dimmer spectra of many such sources.

Once HEAO-2 was launched in 1978, it became possible to accurately measure the X-ray spectra of nearby representative members of each class of extragalactic X-ray source: galaxies, peculiar galaxies (known respectively as Seyfert galaxies, N-galaxies, and BL Lacertae objects), clusters of galaxies, and quasars. Then, numerical trials with computers might determine the recipe by which many very distant members of these classes of objects can blend together to produce the diffuse background. The question was, Do we need a quart of galaxy clusters, a cup of quasars, and just a pinch of Seyfert galaxies to make the observed blend or must the spectrum of the diffuse background be produced mainly by vast numbers of just one kind of source?

In March 1978, Elihu Boldt, a physicist at the Goddard Space Flight Center who is principal investigator for hard X-ray studies by the A2 aboard the HEAO-1 satellite, gave a progress report on the measurements of that instrument. At the annual meeting of the American Association for the Advancement of Science in Washington, D.C., he noted that although less than 5 percent of the data eventually to be collected during HEAO-1's operating lifetime had been received at that time, a basic finding had been made. He told the assembled scientists that the X-ray spectrum of the diffuse background "suggests that it is a thermal emission from a hot plasma at an effective temperature of a half-billion degrees."

Plasma, as the term is used in astronomy, means electrified gas in which electrons have been stripped away from atoms. One interpretation of the HEAO-1 measurements is that Boldt's suggested hot gas may produce the background of hard X-rays that fills distant space in a uniform manner. In that case, given the observed intensity of the X-rays, and the gas temperature as revealed by the shape of the X-ray spectrum, one can calculate the density of the plasma. This computed number turned out to be large enough, Boldt found, that the mass of hot plasma present in space "is about half that required for closure of the universe."

If this observation is correct—and Boldt himself now questions it—then these HEAO-1 observations have a direct bearing on the fundamental cosmological question, Is the universe open or closed? As most people know, the universe was apparently born in an enormous explosion, the Big Bang, about ten to twenty billion years ago and is still expanding. All the clusters of galaxies in space are flying apart from each other as a consequence of the Big Bang. As they fly apart, they are gradually slowed down by the retarding force of gravity. If the density of matter in the universe is sufficiently large, then some day (many billions of years from now), the galaxies will slow down to zero expansion speed and will then begin to fall back together, eventually all to meet in some cosmic catastrophe of the remote future. If this is the case, then the universe is "closed." If, however, the density of the universe is lower than a certain critical value, then the galaxies (although gradually slowing down) will never actually reach zero speed. Like rockets launched from the earth at speeds above the earth's escape velocity, they will fly apart forever. That situation describes an "open" universe.

**CURATOR**
**Takes You Behind the Scenes at Museums**

**CURATOR**, the quarterly publication of the American Museum of Natural History, is of vital interest to anyone who is curious about the museum field.

**CURATOR** examines such broad topics as exhibit making from conception to opening day; the booming use of computers in museums; finances; a museum's obligation to the community; and the curator's role as teacher or researcher.

Outstanding authorities explain their techniques of preparing fossils, restoring pottery, using audio-visual methods of presenting information, or taking a visitor survey in an art museum. Experts share their secrets of coping with an extra elephant, hanging a ninety-two foot model of a whale, or making a store-front museum.

Finally, **CURATOR** reveals plans and ideas for the future of museums.

amount of matter present in space to insure that possibility. Photographs from Palomar seem to show a universe filled with glowing clusters of galaxies, but, in fact, the galaxies are so far apart that the universe consists mostly of dark, empty space, or so it has seemed. Hence the observed density, computed from the occurrence of galaxy clusters, was only a few percent of the critical value required for a closed universe.

If Boldt's 1978 analysis is accurate, however, we have evidence that the density of the universe is at least a substantial fraction of the critical density required for closure. (Analysis of further HEAO-1 data, reported in January 1980 by Boldt and others at the Goddard Center, reduced the early 50 percent estimate to 36 percent, which is still a substantial number.) Whether the universe is open or closed, the A2 experiment (if its measurements have been correctly interpreted) detected and mapped the majority of matter in the universe. That matter is not mainly in the form of visible objects such as stars and galaxies, as astronomers have generally assumed. Instead, it consists mostly of the superhot plasma that apparently fills space between the clusters of galaxies. The plasma is so thin and hot that it shines only in X-rays, not in visible light. However, data from the *Einstein* satellite indicate that the superhot plasma may not exist.

*Einstein* was launched in November 1978. While its measurements and observations are revolutionizing many areas of astronomy, three of its instruments have had special application to an explanation of the source of the diffuse background. Those three instruments, called the IPC (imaging proportional counter), HRI (high resolution imager), and the SSS (solid state spectrometer), have specifically addressed the question of finding the recipe to blend many single X-ray sources to form one diffuse background.

Several aspects are involved in determining whether a "perfect blendship" actually exists. The respective numbers and brightnesses of very distant X-ray sources must be determined and the shapes of the X-ray spectra of each type of source must be learned.

The IPC and HRI instruments were used to detect X-ray emitting quasars and galaxies at far greater distances than previously possible. These instruments made long-exposure X-ray photos of fields of view that were selected in order to avoid the Milky Way and known, relatively nearby galaxies

*The Celebrated Viennese*
**"Ice Fire" Diamond Pendant**

**The lustre of sterling silver . . .**
**the elegance of Austrian crystal . . .**
**the fire of genuine diamond.**

Inspired by the seven million dollar collection of the Imperial Habsburg dynasty, the exquisite *"Ice Fire" Diamond Pendant* is beautifully carved from a solid block of 32% lead-content Austrian crystal* suspended from a 16-inch sterling silver chain and *set with sparkling 1-pt diamond center stone.* (The 1-pt. diamond is *genuine* and accompanied by our Certificate of Authenticity to that effect).

As fascinating and unpredictable as the woman destined to wear it, the *"Ice Fire" Diamond Pendant* can be icily elegant one moment, then flash with the light of a thousand fires the next.

Presented in a velvet and satin gift box, and guaranteed to delight both giver and recipient (or your money gladly refunded), the exquisite *"Ice Fire" Diamond Pendant* is yours for only 14.95. To order, mail coupon or use toll-free phone number below.

and other objects. The location of each bright spot, or "point source" of X-rays, revealed by the photos was measured and furnished to optical astronomers, who used the locations to determine the identity and distance of the objects. Objects found in this way included quasars, galaxies, and foreground stars. In addition, thirty-five already known quasars were photographed with the two instruments, to determine the strength of their X-ray emissions. As a result of this work, a team of investigators at the Center for Astrophysics in Cambridge, Massachusetts, concluded that "a large fraction of the diffuse background is due to previously unresolved discrete sources."

Particular support for this point of view came from the IPC and HRI quasar studies, which were led by astronomer Harvey Tananbaum of the Cambridge group. The Tananbaum study found evidence, as expected, that quasars are at the distances implied by the cosmological interpretation of their red shifts, which states that the shifts are due to the expansion of the universe (see "Quasars Confirmed," *Natural History*, February 1980). Further, by combining the average X-ray emission of a quasar of given visible-light brightness, as determined by *Einstein*, with the relative numbers of quasars of different visible-light brightnesses, as revealed in ordinary telescopic studies, Tananbaum found indications that quasars alone may be present in sufficient amounts in distant space to account entirely for the diffuse background of hard X-rays. In other words, the background may be due to a superposition of discrete sources.

In the meantime, the Goddard astronomers have conducted new studies with the SSS instrument on the *Einstein* satellite. The IPC and HRI instruments told us that there apparently were enough quasars and other individual objects of sufficient brightness to create the diffuse background, but they did not indicate whether these sources have spectra of the right shapes to blend together. In fact, IPC and HRI are soft X-ray instruments and thus measure quasars and galaxies exactly at the wavelengths where, as already explained, the diffuse background from distant space is *not* observed. To believe Tananbaum's conclusions, you have to extrapolate from numbers and brightnesses of quasars and other sources observed in soft X-rays to numbers and brightnesses of the same

objects as they would appear in hard X-rays.

In hard X-rays, however, the technology does not exist to observe so many and such distant quasars as was possible with the soft X-ray instruments. Thus the SSS-instrument studies were addressed to measurements of the X-ray spectra of nearby bright quasars and galaxies. These studies found that the spectra do not have the right shapes. You cannot add together many quasars and galaxies with spectra having the observed shapes and simulate the observed spectrum of the diffuse background of hard X-rays. There probably is a diffuse background of extragalactic origin in *soft* X-rays that arises from quasars, but it is as yet unobserved from the earth because of the interfering flow of soft X-rays from our own Milky Way.

My own conclusion is that the concept of a diffuse background of hard X-rays as produced by individual objects at great distances is not yet proved. Yet the HEAO-1 result, that the background arises from superhot plasma that fills the universe, is also on somewhat shaky ground, and its original proponents no longer believe it.

The most likely resolution of the dilemma comes from the concept of evolution in the universe. The objects whose spectra were measured with the SSS are relatively nearby. That means that the X-rays that have been received and measured from those objects were produced during a relatively recent epoch. On the other hand, the innumerable discrete sources that may make up the diffuse background (if such is the case) must be vastly farther away. That means that the X-rays we are receiving from them were produced during a much earlier epoch in the history of the universe. Perhaps the nature of the objects present in space has changed substantially since then. In that case, the SSS studies of nearby quasars and galaxies tell us only about recent times and give little or no information about the spectra of galaxies and quasars long, long ago. In the early stages of the universe, objects may have been present that had spectra of the right shape to produce the observed diffuse background. If so, then the perfect blendship existed; if not, the universe may be closed and is mostly just a gas.

# Celestial Events

### by Thomas D. Nicholson

**Sun and Moon** The sun is in the constellation Aquarius until the 12th of March, then moves into Pisces, where it arrives at the vernal equinox on the 20th. After mid-April it moves into Aries. The effective equinox (when days and nights are each 12 hours) occurs on March 17, but the sun's center arrives exactly on the equatorial plane on March 20.

Both March and April begin and end with full moons. Phases in March are: full on the 1st, last-quarter on the 9th, new on the 16th, first-quarter on the 23rd, and full again on the 31st. Phases in April are: last-quarter on the 8th, new on the 14th, first-quarter on the 21st, and full on the 30th. A penumbral lunar eclipse (barely dimming the moon's brightness) occurs on March 1. New moon for both months occurs near perigee (when the moon is nearest the earth), two hours before perigee on March 16 and twenty-one hours after on April 14. The effect will strengthen the spring tide on both dates. Apogee (when the moon is farthest from the earth) occurs on March 3 and 30, and April 26.

**Stars and Planets** Get acquainted with the evening planets early in March so you can follow their antics over the next several months. Venus should be first on your list. Now going through a very favorable evening elongation, it pops up in early twilight high in the east, so brilliant that you might mistake it for a landing aircraft (or a "flying saucer"?). It remains in the sky nearly four hours after sundown. Next are Mars, Jupiter, and Saturn, near the bright star Regulus in Leo. Look for them in the east (*opposite* Venus) when it grows dark. Once you find them, you can track them all night long, for they don't set until dawn. Jupiter is easy to recognize, eclipsed in brightness only by the moon and Venus. Mars (ruddy in color and next in brightness) and Regulus are to Jupiter's west (right), while Saturn (about the brightness of Regulus) is to the left and more distant. Once you sort out these four objects, you will enjoy their changes over the next several months. Mars dims rapidly and passes Regulus and Jupiter *twice* each. How? Just watch and see! And the moon will be a special visitor to this group of objects on February 29–March 2, March 27–29, and April 24–25.

February 29–March 1: The moon passes Regulus, Mars, and Jupiter.
March 1: Beginning with Jupiter today, the moon occults Jupiter and Saturn three times each, Regulus and Aldebaran twice each, and Mercury once during March and April, but only two occultations (Aldebaran on March 21 and April 17) occur over North America and neither will be easily seen.
March 2: Mars passes Jupiter at 2:00 P.M., EST.
March 6: Mercury, in inferior conjunction, becomes a morning star.
March 13: Saturn, at opposition, becomes an evening star.
March 17: Mars passes Regulus at 4:00 P.M., EST.
March 19: The moon is near Venus tonight and Aldebaran the 21st.
March 20: Spring begins at 6:10 P.M., EST.
March 27: The moon passes Mars, Regulus, and Jupiter tonight, Saturn on the 29th.
April 2: Mercury, at greatest westerly elongation, is not well placed as a morning star.
April 5: Venus, at greatest easterly elongation, is *very* well placed as an evening star.
April 7: Mars is stationary and resumes direct (easterly) movement.
April 14: Venus passes Aldebaran tonight.

★ Hold the Star Map so the compass direction you face is at the bottom; then match the stars in the lower half of the map with those in the sky near the horizon. The map is for 11:20 P.M. on March 1; 10:25 P.M. on March 15; 9:20 P.M. on March 31; and 8:20 P.M. on April 15; but it can also be used for an hour before and after those times.

# Reproduction by Duplication

*For many plants, cloning is a way of life*

**by Robert E. Cook**

> Cloning is the most dismaying of prospects, mandating as it does the elimination of sex with only metaphoric elimination of death as compensation. It is almost no comfort to know that one's cloned, identical surrogate lives on, especially when the living will very probably involve edging one's real, now aging self off to the side, sooner or later.
>
> Lewis Thomas
> *New England Journal of Medicine,*
> December 12, 1974

People get very upset at the prospect of cloning a human being. We have been quite content to coexist with identical twins since Castor and Pollux, perhaps because such twins are hardly ever identical in the essentials of life. But the possibility, although remote, of taking a cell from one human being, and with it creating such a twin, has generated public anxiety, numerous ethical questions, much rhetoric, and on occasion, a touch of eloquence.

Plants, on the other hand, are quite casual about cloning, with hardly an ethical glance at the prospect of a world populated by multiple copies of themselves. Many plant species, perhaps most, have evolved the ability to reproduce asexually by one means or another, whether it be the ground-level runners of strawberries or the delicate, asexual seeds of dandelion, hawkweeds, and blackberries. Asexual reproduction in plants is like growing itself; it is done with all the ease and facility of producing a new branch.

In fact, many botanists prefer to call this process clonal growth rather than asexual reproduction. But their preference arises from focusing on the process. The result—a genetically identical daughter plant that eventually becomes physically separate and physiologically independent from the mother—suggests that reproduction of a sort is indeed taking place.

Take the starflower, for example. This modest little forest herb emerges early in spring with five to eight whorled leaves at the end of a delicate stem and, sometimes, a tiny, white, seven-petaled flower rising above them. Throughout the summer the plant produces no new leaves; the real action is occurring below ground.

In late June, one or more underground stems grow from the base of the shoot and snake their way through the tangled mass of roots, rocks, and litter lying just below the surface of the forest floor. In July, as the days begin to grow shorter, the entire metabolism of the individual changes. Nutrients are shunted from the mother plant to the thickening tips of the underground rhizomes, where they are stockpiled as proteins and starch to form a swollen tuber complete with quiescent bud. In August the whorl at the summit begins to yellow and senesce, and the plant transports the nutrients in the foliage to parts below ground.

By October the mother plant has fully disintegrated, as have the underground connections to her newly formed and genetically identical daughters, which may lie up to three feet apart. The daughters in turn remain dormant through winter and commence growth with the warming of the soil in spring. They emerge through the litter in May, provisioned by the tuber until newly formed leaves begin photosynthesis. What was once a single plant has now become two, and sometimes three, physiologically independent individuals.

Although the starflower displays a rather modest rate of duplication appropriate to its shady understory habitat, there are some very impressive clones that carry on rapid self-replication for ages. Grasses, for instance, can acquire new ground through tillering, a process in which a bud at the base of a blade begins to grow sideways, soon rooting to form a new shoot beside the parent rosette of leaves, and tillering in its turn. With time the original physiological connection between parent and offspring becomes dormant and decays. Such clumps of grass may vary in size and density depending on how much lateral growth occurs before the growing bud roots and sends up a shoot.

Swedish botanist Daniel J. Harberd became curious about how large such clones might grow in old pastures and grasslands. He knew that plants of identical genetic constitution are self-incompatible, that is, individuals within the same clone cannot form successful seed when the male pollen of one lands on the female pistil of another. Such a system, somewhat the reverse of graft incompatibility in man, has evolved in many species to insure the exchange of pollen between genetically different individuals.

With large-scale sampling and crossing experiments Harberd identified different plants that had arisen from a single seed through sequential tillering. To his surprise, he found in one pasture a clone of the common red fescue, *Festuca rubra*, which stretched more than 240 yards. By calculating the rate of tillering, Harberd estimated the plant was more than a thousand years old.

In a second study Harberd found an entire pasture of creeping soft grass, *Holcus mollis*, dominated by only four genetically different types, one with shoots growing almost half a mile apart. Such clones, capable of continual expansion through great tracts of

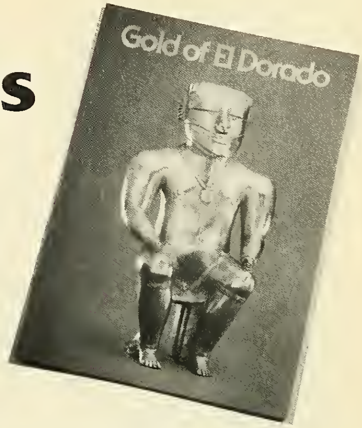
# An Art Book That Took Centuries To Create



It took the American Museum of latural History four years to arrange its xceptional exhibition of more than 500 ieces of ancient gold from Colombia. 3ut those few years are a brief time vhen compared with the decades archeologists have spent digging (literally!) ind studying the gold artifacts from ombs, caves, and buried sites. And all hat time is short when compared with he many centuries prehistoric Indians racticed their craftsmanship and artisry to create these treasures.

So when it became the United States ponsor for this outstanding collection, he American Museum faced a dilemma. ould we do justice to all this effort and cholarship and beauty? We think we ave. First, by dramatically displaying *3old of El Dorado: The Heritage of Coombia* in one of our largest halls. The lowing reports from visitors tell us our fforts have been worthwhile. If you lon't have a chance to see the show for ourself in New York, we hope you will ee it in Chicago, San Francisco, or New )rleans on its year and a half tour.

The second challenge for the Amerian Museum was the creation of an ppropriate book to accompany the exibition. We decided against a tradiional catalog; against a small, boring olume with tiny black-and-white picures that could never do justice to these ine objects. Instead, we decided to preent a select number of the finest pieces f pre-Columbian gold in a large, stuning format. And to represent the three mportant elements that make a great rt book we chose outstanding profesionals.

First, photographer Lee Boltin. One f the greatest photographers of art obects, he also took the famous pictures f the Tutankhamun show. We sent him broad to find and record great pieces f pre-Columbian art.

Second, archeologist Warwick Bray, rom the University of London. One of he world's foremost authorities on preolumbian art, Bray is also a skilled writer, able to present fascinating background in a succinct, readable essay in the book. Dr. Bray organized the Colombian gold exhibition in London.

Third, Harry N. Abrams, Inc., America's leading publisher of fine art books. In a co-publishing venture with the American Museum, Abrams designed the book, supervised the preparation of 30 large color plates, and monitored the fine-quality printing.

The result is an unprecedented exhibition book. It is bold and big—each plate is 16 by 11½ inches—bigger than this magazine *opened up*. The paper is heavier than most posters. In fact, many persons have purchased two copies of the book in order to have one set of these fine art prints for framing.

And now for the happy ending. Because the Museum is a co-publisher, we are able to offer this soft-bound art book at a major savings from its normal retail price of $12.50. We are pleased to offer *Gold of El Dorado* to subscribers for only $8.95—a 28% savings off its regular price. This special offer is valid only during the exhibition and only while our limited supply lasts. We suggest that you order one or more copies immediately. Of course, if you are not satisfied after you have had an opportunity to examine it in your home, simply return the book and the Museum will refund the purchase price.

space and time must possess phenomenal abilities to withstand the vicissitudes of climate and terrain.

The clonal record for size and age, however, appears to be held by the quaking aspen, *Populus tremuloides*, found in unglaciated portions of the Rocky Mountains in Utah. New shoots are formed by buds that sprout from the roots of a mature tree, and this clonal growth is greatly stimulated when fire or avalanche suddenly destroys the mother stem. Some clonal stands cover such vast regions of rugged mountainside that they were originally mistaken for separate races of aspen. In 1921 Frederick S. Baker of the U.S. Forest Service wrote:

> In the spring when the leaves are unfolding it is commonly noted that the leafing time of adjacent bodies is quite dissimilar. Not infrequently a line can be traced for upwards of a mile through the aspen where on one side the leaves are half developed and on the other the buds are just bursting. This line is almost invariably clear-cut and distinct with little intermingling of the two forms. . . . The writer confesses an entire inability to explain the causes of these two widely distributed, but distinct and closely intermingled races of aspen.

Their true nature remained hidden for fifty years until aerial photographs revealed clones occupying more than 200 acres. One genetic individual was represented by more than 47,000 trees. And the trees were of considerable size and age, one hundred years old on the average. The age of the entire clone is unknown, although in Minnesota, an aspen clone covering several acres probably dates from the last glaciation 8,000 years ago.

Trees that clone usually do so through the production of root sprouts, and many herbaceous plants form new shoots from the main stem through buds that grow for varying distances beneath the ground before initiating a new plant. Other species, such as the succulent herb *Kalanchoe*, are able to fabricate tiny plantlets in notches at the margins of their foliage; these plants eventually fall to the soil surface, begin growth, and establish a colony surrounding the mother.

Somewhat similar in consequence, although different developmentally, is the ontogeny of apomictic, or asexual, seed in numerous species, of which dandelion (*Taraxacum*) and hawkweed (*Hieracium*) have been mentioned. In some cases a cell in the ovary wall, genetically identical to all the other cells in the mother's body, may initiate the normal steps of seed formation. In other species there is a failure in reduction division, the usual process whereby the female egg is created with half the mother's genes in anticipation of fertilization by the equally reduced male pollen. In such instances the egg, containing a full complement of maternal genes, may actually require the chemical stimulation of male pollen without actual fertilization before beginning normal seed development. Apomictic seeds combine the advantages of cloning with the power to disperse offspring great distances.

But what are the advantages of cloning? The answer depends very much on one's perspective. Certainly, plants that are able to survive for thousands of years are doing well by any standards. The problem appears when one tries to decide what is meant by "the plant." Through the eyes of a higher vertebrate unaccustomed to asexual reproduction, the plant of significance is the single stem that lives and dies, the discrete, physiologically integrated organism that we harvest for food and

A typical dinner from *Chez Valentin* in Treichville, Ivory Coast, might offer an appetizer of country pate, smoked salmon, or a mound of chunked lobster in a delicious cream sauce. For an entree you might enjoy a rack of baby lamb or "Veal Africain," which is a veal cutlet wrapped around a banana and topped with a delicate curry sauce. As for dessert, perhaps a flaming rum omelette filled with fruit, or a baked Alaska. As you can see, the pleasures of the palate prevail in West Africa. Bon Appetit!

The roots of American soul food go back to West Africa. When you go there you'll find greens, yams and barbecue galore.

**Baked Alaska in Africa?**

If your experience of the peanut is limited to roasted goobers or a peanut butter and jelly sandwich, you've got new worlds to discover in West Africa. Start with a flavorful chicken-groundnut stew, then move on to a score of delicious dishes that feature these luscious legumes.

Now what are you waiting for? Isn't it time you discovered West Africa? Just call your Travel Agent or your nearest Air Afrique/Air France office today. Hurry!

West African cooks took the versatile okra plant to the heights of culinary excellence and gave the world a soup called gumbo.

AIR AFRIQUE

Africa begins with Air Afrique.
And it's just seven hours to the New Sun...
West Africa.

er. From an evolutionary perspecve, however, the entire clone is a ngle individual that, like you or me, ad a unique time of conception and ill have a final day of death when its st remaining stem succumbs to age or ccident.

Natural selection will perpetuate hose combinations of genes that, in a articular environment, manage to surive and replicate identical or closely lated combinations. Clones represent ombinations that have achieved sucess in an evolutionary sense by parating the genetic individual into any different physiological individals. Each of these physiological units ay be termed a ramet, while the entire one, consisting of all ramets derived om a single fertilization of pollen and g, has been aptly called the genet by hn Harper, a plant ecologist at Uniersity College of North Wales. arper has stressed that it is the genet pon which natural selection operates. a large, widespread clone the death f a ramet may have as little evolutiony consequence as the pruning of a ranch in a large tree or the loss of a g in an insect.

Cloning has some definite advanges for species that produce many mets. First, it is a form of growth, increase in size through the initiaon of lateral shoots. As such, it enances the ability of the genet to acuire additional resources and, ultiately, to produce an abundant crop of eds. In this sense cloning is no difrent from a large and healthy tree rowing additional limbs. But while aks and maples produce tall trunks nd overtop other individuals, a preading clone subverts from ithin—or rather beneath. While still ceiving sustenance from the mother lant, a daugher shoot may be able to tablish itself with roots and green foage right in the midst of a dense stand f other individuals.

This is how grasses gradually acuire turf, and the process has been ptly compared to guerrilla warfare. At s leading edge, a large genet, extenvely interconnected, presents an rray of advanced raiders, each provioned by an elaborate logistical netork occupying already conquered terain. The tactical advantage of this ompetitive strategy depends upon the hysiological capability and duration f the supply lines among ramets.

An additional possible advantage of oning—conceptually distinct from e guerrilla tactics—involves spread-

ing the risk of mortality for the genet among many separate ramets. Here the advantage depends on a physiological and spatial isolation among stems such that the death of a ramet is an independent event. An individual ramet may suffer an alarmingly high probability of dying, but the risk to the genet grows smaller as the number of ramets increases.

This spectrum of benefits—growth, competition, spreading the risk of death—is reflected in the diversity of mechanisms whereby different species grow and reproduce asexually—from the large, integrated clones of prairie and meadow grasses to the floating seeds of dandelions, which are independent from the moment of dispersal from the mother plant. The relations of dependence and independence between mothers and daughters are of considerable ecological and evolutionary interest, but very little work has been done to understand them.

Some interesting experiments have been performed, however, in grasses, such as Italian ryegrass, *Lolium multiflorum*, using carbon dioxide that contains radioactive carbon. The leaves absorb the $CO_2$ and, through photosynthesis, create sugars that are distributed to other parts of the plant, carrying the "hot" carbon with them. By sampling leaves of the mother plant and daughter ramets at different times after exposing the mother to radioactively labeled gas, the experimenter can trace and quantify the supply of nutrients. During the development of a daughter tiller, or ramet, the flow of carbohydrates from the mother gradually decreases as the new shoot initiates its own roots and leaves. Interestingly enough, the umbilical cord does not decay as the flow of resources dwindles, but remains dormant for some time. When the daughter shoot is artificially pruned, maternal sustenance resumes immediately, allowing the injured offspring to produce a new set of foliage.

Similar studies among aspen ramets have shown that the potential for integrated physiologies may survive for years. In the sweet white violet, *Viola blanda* (with which I am working), the ties between mother and daughter last for only three or four years, while the asexual offspring of the starflower are on their own at the end of each growing season.

If clonal growth and reproduction are so successful, why should these species bother with sex at all? While this could be the subject of another essay, I can say that many do not or do so only infrequently. More precisely, one is often hard pressed to find new sprouts from seed in the vicinity of large and successful clones. In the vast tracts of pasture grasses Harberd studied in Sweden, he seldom found a young seedling, and he suggested that, were one to germinate, it would stand little chance of survival among the traffic of vigorous tillers. Anyone who has really looked at such perennial herbs of the forest floor as lilies and wood asters knows that they seldom reproduce by seed. These findings, coupled with the astounding size and age of some clones, suggest that the successful establishment of new genets is a rare event, and that the appearance of seedlings is often associated with some disturbance that removes the competitive advantage of existing vegetation.

A particularly nice demonstration of this can be seen in the work of Eino Oinonen, a Finnish botanist who made an extensive survey of the bracken fern *Pteridium aquilinum* in southern Finland. He first observed that many large clones were growing in the vicinity of villages and road junctions, and after measuring their ground diameter, guessed that their size and age were related. He also knew that the sexual spores of this fern require sterilized soil for germination, a condition often associated with fire.

To confirm his hypothesis of great age and historical origin, he traced the records of encounters between combat troops during the numerous Russo-Finnish wars that periodically brutalized the landscape from the thirteenth century to the Second World War. (In addition to the numerous fires spawned by battle, Russian soldiers baked bread in small ground-pits, which marked their encampments along lines of march.) Remarkably good correlations could be seen between the size of clones found in particular locations and the history of local troop movements.

All of this research suggests the following generalized spectacle of genet and ramet dynamics through time. The curtain rises with the massive destruction of vegetation by some disruptive event such as fire or flood. Numerous new seedling genets germinate from seeds lying dormant in the soil. As it grows and ramifies, each genet sends out runners and advanced shoots (ramets), until contact is made with another genet. The landscape is rapidly occupied by plants, and a long, proracted combat sets in with intertwinng ramets battling for scarce resources f light and nutrients.

Many die at the front, succumbing o prolonged darkness and decay; thers advance, supplied from the rear nd taking advantage of temporary aps in the opposing canopy or patches f disturbed turf. Over long spans of ime, one genet, perhaps not as well dapted to the terrain or with many ewer shoots when contact was made, radually loses more ramets than it can eplace and slowly retreats to more ospitable ground. Numerous small nd imperfectly adapted genets are uickly invaded and conquered. After ix thousand or so years of intense conest only four or five remarkable genets urvive, their precise center of distriution determined more by the accilents of germination than by the perormance of the average struggling amet. Still, at the edges of their terriory they continue to skirmish, each well entrenched and none able to oust he others. Only apocalyptic disaster an terminate the struggle and establish new set of genetically reconstituted ombatants.

Very high drama indeed, but does it eally represent what is happening in ature? There is some suggestive evience. Lin Wu, a student of the Engish geneticist Tony Bradshaw, used lectrophoresis to examine the clone tructure of different populations of edtop, or creeping bent, *Agrostis stoonifera*, which produces clones hrough the vigorous initiation of runers. By extracting proteins chemially and separating them in an electric eld, he was able to determine whether wo plants were likely to be members f the same genet. After extensive ampling and statistical analysis he ould identify the total number of lones in a population.

Bradshaw had long maintained an nterest in populations of grasses growng on soils contaminated with heavy metals, such as lead or copper from ocal mines and refineries. Within hisorical times such grasses had evolved tolerance for the toxic presence of the netals, and Bradshaw suggested to Wu hat he examine the number of genets rowing in grass lawns sown on refinry soils at known times in the past.

He chose lawns that were eight, ourteen, and seventy years old; for a ontrol, he examined the genets of two ntolerant redtop populations growing n uncontaminated soils as lawns of reat but unknown age. To his surprise Wu found that there were many more genets surviving in the refinery populations than in the nontolerant lawns, despite the stringent intensity of natural selection on contaminated soils. In fact, each of the control populations contained only two genets, and Wu and Bradshaw could not believe that this reflected the number of successful seedlings at the time of establishment.

Apparently, extensive genet competition and elimination had long been occurring. Equally surprising, and somewhat puzzling, was the discovery that despite quite different ages all of the tolerant populations were composed of roughly the same number of genets, as though genet warfare on toxic soils had not been occurring.

The explanation came in an examination of the structure of the clones. The eight-year-old redtop consisted of isolated clumps slowly expanding outward. The fourteen-year population displayed coalescing patches of grass initiating contact, with bare islands of soil between. The seventy-year-old lawn was continuous. Wu and Bradshaw speculated that the severe conditions for growth in contaminated soil had accelerated selection for tolerance but delayed the inevitable competitive struggle between tolerant clones. This suspicion was further confirmed when a third, uncontaminated population, growing under harsh conditions near a sea cliff, was found to have a high number of clones. In a sense, then, the adverse conditions of rigorous and stressful habitats may actually maintain a high diversity of genets rather than eliminate them.

We don't know very much about the real biology of most clones growing in nature. Almost no theory and little experimental work has explored the physiological relations of kinship between mothers, daughters, and granddaughters. Determining the consanguinity of a whole community of intermingling shoots is a difficult task at best, and the vast time scale upon which clonal competition appears to be occurring often renders direct tests of historical explanations impossible. But a start has been made, perhaps most importantly in the realization, reflected in the conceptual distinction between ramets and genets, that the laws of natural selection are not constrained by human notions of individuality.

# The Foxes of Hokkaido

Fox Family, by Minoru Taketazu. *John Weatherhill, Inc., $25.00; 139 pp., illus.*

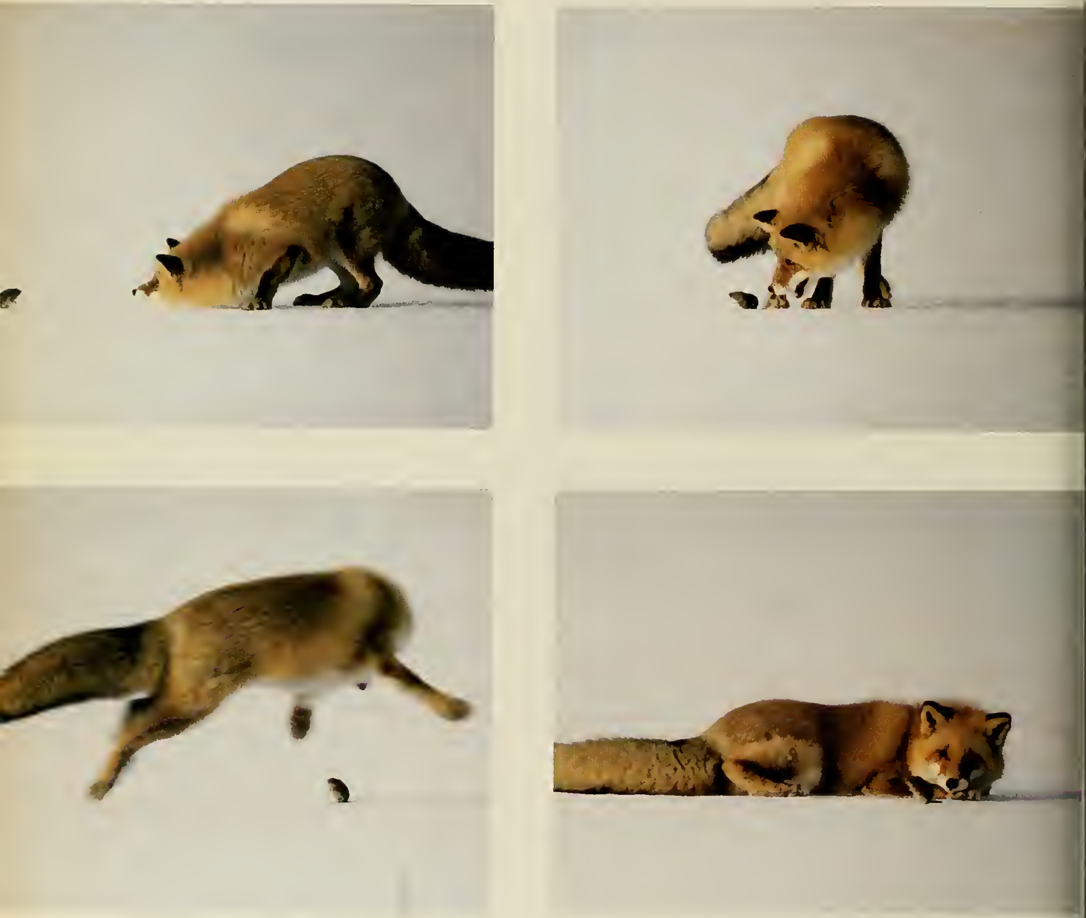
There is a Japanese folk tradition that claims foxes have the power to bewitch human beings, and Minoru Taketazu, author of *Fox Family*, may be living proof of the validity of this old belief. Taketazu, a veterinarian with all the inclinations of a wildlife biologist, has devoted fourteen years to the study of the foxes of Hokkaido, Japan's northernmost island. In 1966, he began observing the Hokkaido fox—a local variety of the red fox—on a regular basis, becoming more and more fascinated with these animals as they became used to his presence and he was able to follow their daily routine. His book presents a seasonal account of their lives, starting with their winter breeding on the ice floes of the Sea of Okhotsk and continuing with the spring birth of the cubs and the rearing and training of the young for the inevitable separation in autumn.

Complementing the narrative and forming the body of the book are remarkable photographs that illustrate the behavior of the fox. Taketazu, who denies he is a professional photographer, spent twelve years taking photographs, and those reproduced in this book were chosen from some 70,000 shots. And what wonderful shots they are: foxes mating, fighting, playing, hunting, romping in dandelion-covered fields, or traveling over a vast, snowy countryside. A series of four photographs shows a vixen, perhaps too full to eat, playing with a mouse much the way a cat does. Many of the photographs center on the cubs, from their first emergence from the den at about two weeks of age through their training to hunt and survive on their own. Foxes have exceptionally well-developed senses of smell and hearing. Detecting the presence of a mouse in the undergrowth, the fox leaps into the air in a graceful arch, then falls on its prey with muzzle and front paws. There are a number of photographs of this hunting technique, apparently more picturesque than effective since the author observed one vixen repeat her leap fourteen times to catch a single mouse. There is such vitality and movement in these photographs that they appear to be the frames of a motion picture.

At the end of the book, there are commentaries for the photographs, keyed to small black-and-white duplicates of the pictures, and a general discussion of vulpine biology.

*Carol Breslin*

*"The vixen's hunting range has extended to the farmlands and the ponds beyond. As I watch her go out, I wonder—probably together with the cubs—what she will bring home for supper. . . ."*



*"On one rare occasion when this vixen was full, she came upon a mouse, and instead of eating it, she observed its motions and did no more than play with it for a few minutes."*

*'Windless days are the best for unting. If they listen carefully, he cubs can hear the footsteps f small animals at the bases of he wild poppies. As soon as they ear a sound, they leap up and ounce on the clump of grass rom which the sound came."*

### RATE AND STYLE INFORMATION

$1.75 per word, 16 word ($28) minimum. *Display classified* is $150 per inch. All advertisements must be prepaid. Rates are not structured for agency or frequency discounts. All advertisements are accepted at NATURAL HISTORY's discretion. Send check/money order payable to NATURAL HISTORY to: The Market, NATURAL HISTORY Magazine, Central Park West at 79th St., New York, NY 10024 Please include your personal address and telephone number, issue preferred, and suggested heading. Deadline—8th of month, two months prior to cover date (the January issue closes Nov. 8). Camera-ready art is required for display ads. A tearsheet or copy of the page with your ad will be sent upon publication.

Box numbers, telephone numbers, and hyphenated words count as two words; abbreviations and zip codes as one word each. All states are shown in two-letter code followed by zip, then telephone (with area code), if desired. Occasionally, slight editing is required for clarity. Thank you!

# Additional Reading

**Bhutanese Dances** (p. 38)

*The Sacred Dance-Drama of Bhutan*, an informative four-page monograph by Mynak R. Tulka, can be ordered for $4.50 from the Asia Society, 133 East 58th Street, New York, New York 10022. It is part of a packet that includes monographs on Burmese dances and Korean court music and dance. The Asia Society also has a thirty-minute color film, *The Royal Dancers and Musicians from the Kingdom of Bhutan*, for rent or sale. A complete study of the *cham* tradition, *Tibetan Religious Dancers*, by René De Nebesky-Wojkowitz (The Hague: Mouton, 1976), contains the text and translation of an important dance manual composed by the fifth Dalai Lama. Michael Aris discusses the traditions of *cham* in "The Admonition of the Thunderbolt Cannon-ball and Its Place in the Bhutanese New Year Festival" (*Bulletin of the School of Oriental and African Studies*, vol. 39, part 3, 1976, pp. 601–35). *Tibetan Civilization*, rev. ed., by R. A. Stein (Stamford: Stamford University Press, 1972), is on Tibetan culture.

**Toads and Tarantulas** (p. 48)

For a discussion of the relation between some insects and spiders, see "Spider and Fly Play Cat and Mouse," by William G. Eberhard (*Natural History*, January 1980, pp. 56–61). Tarantulas are discussed in *American Spiders*, by Willis J. Gertsch (Princeton: D. Van Nostrand Co., 1949), and in Gertsch's revision of John Henry Comstock's *The Spider Book* (Ithaca: Cornell University Press, 1975). Relationships of toads and tarantulas are mentioned in R. Conant's *Field Guide to Reptiles and Amphibians of Eastern and Central North America*, second edition (Boston: Houghton Mifflin Co., 1975), and in *Reptiles and Amphibians of North America*, by A. Leviton (New York: Doubleday and Co., 1976).

**Iule Deer** (p. 56)

Well illustrated, *The World of the Vhite-tailed Deer*, by Leonard Lee ue III (New York: J. B. Lippincott o., 1962), draws upon years of data athering for its description of the life f the deer and includes a bibliogıphy. ‘‘Foods of the Rocky Mountain Iule Deer,’’ by Roland C. Kufeld, ı.C. Wallmo, and Charles Feddema JSDA Forest Service Research Paper M-111, July 1973), is a short paper ith an extensive bibliography. A genal book that provides information on iule deer is Raymond Edwin Chapn's *Deer* (Poole: Blandford Press, 977). *The Deer of North America*, lited by Walter P. Taylor (Harrisurg: Stackpole Co., and the Wildlife lanagement Institute, Washington, ı.C., 1956), is comprehensive but ated. A similar work, *Mule Deer and lack-tailed Deer*, edited by O.C. Vallmo will be published soon by tackpole.

**rill** (p. 66)

*The Encyclopaedia Britannica*, fifenth edition, s.v. ‘‘krill’’ in the *licropaedia*, gives a brief description ıd references to articles on ecology, iology, behavior, and the relation of rill to the fishing industry. G. A. lano's article ‘‘Antarctica—the Livıg Legacy,’’ in the *1980 Year Book f Science and the Future* (Chicago: ncyclopaedia Britannica, 1979, pp. 46–71), discusses the role of krill in ıtarctic ecology. A general descripon of the animal can be found in Krill,’’ by J. F. Lohr (*Oceans*, Iay/June 1977, pp. 54–55).

*Enter the world of Questers nature tours.*

When you travel with Questers, you have the advantage of our knowledge of the travel world. And our experience of the natural world We are travel professionals. And our only tour program is Worldwide Nature Tours.

Under the leadership of an accompanying naturalist, we search out the plants and animals, birds and flowers . rain forests, mountains, and tundra . seashores, lakes, and swamps of the regions we explore. At the same time, we include the more usual attractions in touring—the cities, archaeological sites, and people.

The current Directory of Worldwide Nature Tours describes 29 tours varying from 9 to 36 days and going to virtually every part of the world. Included are The Amazon, Peru, Patagonia, Galapagos, Hawaii, Alaska, Death Valley, Everglades, Ladakh, Sri Lanka, Iceland, Scotland, Greece, Australia, and New Zealand Tour parties are small, the pace leisurely, and itineraries unusual

*Call or write Questers or see your Travel Agent today for your free copy of the Directory of Worldwide Nature Tours*

Discovery Tours

alaskan wildlife adventure

**June 20 to July 6, 1980**

A journey to America's last great frontier. Cruise through fabulous Glacier Bay, with its whales, seals and teeming birdlife. Explore scenic Mt. McKinley National Park, and see giant moose, white mountain sheep, barrenground caribou, golden eagles. Visit volcanic Katmai, and watch brown bears fishing for salmon. Fly to the remote Pribilof Islands, summer home to over a million fur seals and countless nesting sea birds. Enjoy exciting wildlife in wilderness areas almost untouched by civilization. Led by Kenneth A. Chambers, Lecturer in Zoology at the Museum. For further information write to Discovery Tours, American Museum of Natural History, Central Park West at 79 St., NY NY 10024, or call (212) 873-1440.

# The Giant Snail of La Jolla

*Commercial divers, sportsmen, and otters pursue the tasty abalone*

Emma Stark Hampton, Daughter of the American Revolution and the distinguished Michigan lady after whom my Detroit elementary school was named, had in her time put together a stylish amateur collection of rocks and fossils, fish bills, and shells, which came eventually to rest in an unlabeled heap in a disused closet at the Hampton School. The principal, a canny bureaucrat who had been frequently pressed by my mother to "enrich" my educational program, seized upon the neglected Hampton trove as an ideal extracurricular project that would occupy my vaunted intellectual curiosity and also give the school its own museum of natural history.

While other children sat in class, studying the art of the paper wad, I attended to my curatorial duties. Completely ignorant of biology and geology, I spent many happy hours leisurely familiarizing myself with the objects but not making much progress toward their positive identification. Fortunately, an older boy named Larry Fishman, who had a modest grasp of the relevant science, was my cocurator. He knew a trilobite when he saw one, and he was also able to tell me that certain large, flattish, nacreous shells with holes in them were abalones.

In that inland setting, where clams and oysters were exotic beasts, it never occurred to me that the gastropods that had once lived in those iridescent shells were edible. But like many other Midwesterners, when I grew up, I made my way to California, off whose shores various species of the abalone genus, *Haliotis*, cling to underwater rocks and feast on kelp. Californians justly prize the muscular flesh of the foot, sometimes almost twelve inches long, that holds this marine snail in place. Indeed, abalone is such a delicacy along our southern Pacific coast that it is possibly the most expensive indigenous American food, at roughly fifteen dollars a pound in markets, because it is so scarce. Commercial divers and sportsmen with scuba rigs have pursued abalone so avidly that good beds are harder and harder to find. And now that the sea otter is environmentally protected, this natural predator of abalones is extending its range and further depleting the haliotian supply.

This abalone dearth sounds like a typically modern problem in which overfishing, high population density, and ecological tampering have decimated a mollusk that had happily carried on its vegetarian life cycle in American waters for millenniums before the coming of our advanced civilization. This scenario is true enough as far as it goes, but the wholesale assault on the abalone actually began very long ago and must qualify as one of the earliest human depredations of the American biomass.

In the kitchen middens of Indians who lived on what is now Catalina Island, west of Los Angeles, about 4000–3500 B.C., Clement W. Meighan found shell remains indicating that even then, without benefit of high technology, the abalone had started its up-and-down career as a sometimes endangered species.

In the lower strata that he excavated, Meighan found a predominance of abalone shells. They outnumbered the next most abundant genus, *Mytilus* (mussels), by a ratio of 4 to 1. In the upper levels, the ratio had reversed. Evidently, the Indians, preferring the abalone to other shellfish, had eaten their way through the abalone beds and then switched over to mussels when abalones became scarce.

Although contemporary Californians may seem to be repeating the process, they have not yet switched to mussels because of toxic pollution and a dietary phobia against them. Fortunately, they also have taken some measures to turn the tide in favor of the abalone. In a former sardine cannery in Monterey, George S. Lockwood is at work perfecting a commercially viable abalone farm. Through careful, enriched feeding and controlled light and temperature conditions, he hopes that maricultured abalones will put on their desired weight twice as fast as the ten years they would normally take in the wild. Lockwood also sells small abalones to the California Department of Fish and Game, which plants them in the ocean.

More prosaically, Fish and Game patrols set up abalone fishing areas to enforce the strict regulations enacted to protect already established natural beds. Sport divers are permitted a maximum of four abalones a day, and these cannot legally be stockpiled in the refrigerator since it is against the law to possess more than four at a time. There are also rules about minimum permissible length. Red abalones, the largest species, have to be at least seven inches; pinks and greens, six inches. Tougher, less desirable blacks, which

### by Raymond Sokolov

ing to rocks in the surf, are legal at ve inches.

Divers measure their take underater with the irons they use to pry eir prey loose from the rocks. These ng flat blades are marked off at five, x, and seven inches, and by law, they ust not be thinner than an eighth of inch so that they don't cut the abane. Since abalones have no clotting ent in their blood, a cut means cerin death, making it futile for divers put back those that are too small.

Despite all these apparently stultifyg regulations and what may sound e a tedious amount of time spent ecking length, catching an abalone still mostly a matter of stealth and eed. Give the gastropod warning that you are there and it tightens its grip on the rock, tightens it so that its potentially delectable foot exerts a force of 400 pounds per square inch. In practice, once this happens, the game is up: the hapless diver cannot pry the abalone loose. Good abalone hunters slip the blade swiftly under the foot and pull immediately. Hesitation lets the animal seize the blade, and once that happens, hard prying can do little more than bend and break the metal.

"The new diver has a difficult time," says Bert Kobayashi, a Ph.D. in marine biology from the Scripps Institute of Oceanography at La Jolla, who supervises the physical education program at the University of California, San Diego. Kobayashi also teaches scuba classes and is the guiding light of the UCSD diving club, known as the Sea Deucers.

Photographs by Craig Arness

Recently I went with Kobayashi and the Sea Deucers out beyond the famous surf that pounds into Black's Beach in La Jolla. With the town's sheer sandstone cliffs behind us, we pitched and rolled out into the chilly, fifty-degree Pacific in an inflated boat, until we came to a field of kelp. The water was about sixty feet deep where we dropped anchor.

"Right down the anchor line," said Kobayashi in his bass announcer's voice. "Let's do it." Several wetsuited bodies with breathing apparatus flipped backward into the ocean and disappeared except for the constant stream of bubbles they sent up to the surface.

Feeling queasy from the movement of the boat while I sat waiting, I tried to relieve the nausea by staring at distant points on the shore. We had come quite far out to sea, I thought. As Kobayashi had told me, "It has gotten harder and harder to find abalones. There are still areas that appear to be virgin, but even there the average size has decreased."

A pod of curious sea lions swam around the boat, distracting me periodically from the cliffs, which are really the visible portion of an immense undersea canyon whose walls cause La Jolla's splendid surf. Surfers, little black dots much farther in, were out in force riding the big waves.

After a few minutes, Kobayashi emerged with a bag of red abalones, the world's largest *Haliotis*. Some of the other divers had found them too, but the dive had been particularly hard because the surge of the waves had reached down abnormally deep and roiled the bottom, sweeping the Sea Deucers along at a speed that disrupted the intricate search and surgical lunge of abalone fishing. Even so, they had pried loose enough abalones to make a meal for all of us.

After red abalones have been shelled, cleaned, and cut into several thin slices, two of these big univalves will generally feed three people. But getting to the cooking stage with abalones is quite a job and, among other things, requires a grasp of abalone anatomy and physiology.

On the outside of the elliptical shell, near one of the long outer edges, is a line of holes. The animal's gills are behind the holes, which are outlets for water expelled from the gills. There is a lip on the inner rim of the shell on the side with the holes. The opposite side has no lip, giving easier access to the abalone iron.

You set the abalone on a table upside down (with the foot up) and insert the iron between the flesh and the shell, pushing down as far as it will go and then pulling it back and forth while exerting some pressure upward, until the muscle pops loose from the shell. Done properly, this maneuver will remove the abalone in one piece from the shell, which has a beautifully iridescent interior, really a muscle scar where the foot was once attached. Sometimes a tiny, dark shrimp, *Betaeus harfordi*, drops out of the shell. It is a commensal organism, sharing shelter and meals with the abalone.

Along with the muscular, edible foot comes a large blob of gonads—green in females, cream colored in males. Discard these and cut away the black skin and the leathery outer layer of the foot. What remains is a thick wedge of hard abalone muscle. It has to be sliced as thin as possible, which can be done in a trice with a professional meat slicing machine, the kind used in delicatessens. The Sea Deucers had improvised special boards with two metal rods set in them (or in one case, two thin strips of wood). Kobayashi showed me how to set a large, very sharp knife flat on the supports and use them as a guide. With the abalone placed between the knife supports it was possible to slice through the bottom of the muscle, making a transverse cut about an eighth of an inch thick. He removed one slice and then kept on slicing in this manner until the entire muscle had been reduced to several scaloppine, which should be chilled for three hours to relax the muscle. Then you pound them with the same kind of toothed mallet that is sold for flattening veal scaloppine.

This is not an optional step. An abalone cannot be eaten until each slice has been thoroughly pounded into flaccidity. At first, when you pound, the slices curl up as if alive. You turn them over and pound some more until finally you have a docile, extremely thin piece of meat, but you must not pound so energetically that you turn the abalone to mush or cut it to fragments.

Kobayashi soaks pounded abalone slices in milk or beer. Then he dredges them in seasoned cracker meal. Bread crumbs or cornmeal would also work well. Once you have done this, it is at last time to sauté the abalone in hot oil. When they are golden brown, you eat them, saying a little prayer so that conservation and mariculture will prevent the extinction of this very fine gift from the sea.

### Seafood Simmer

(Adapted from *The Northwest Cookbook*, by Lila Gault)

- 4 tablespoons butter
- ¼ cup dry white wine
- 1 tablespoon shallots, peeled and finely chopped
- 1 tablespoon parsley, finely chopped
- 2 large abalones, sliced, pounded, and cut into strips
- 2 large scallops, cut into pieces

1. Melt butter in a medium skillet over medium high heat. When bubbling subsides, add wine and boil for a minute or so.
2. Add shallots and parsley and cook over medium heat for 2 minutes.
3. Add shellfish. Cook for 5 minutes, stirring occasionally.

Yield: 3–4 servings

# Gulf is van pooling.
# Because one van is worth 1,000 gallons.

*"I'm full-time Program Administrator and part-time driver. Here's my group."*

"Every morning, 1,749 Gulf employees who used to drive their own cars to work now make the trip in vans," says Gulf's van pooling Program Administrator Ken Sawicki. "And the energy savings are really amazing.

*"Every van we operate saves 1,000 gallons of gas every 38 working days."*

"With 11 people to a van making an average daily round trip of about 50 miles, we figure that each van saves 1,000 gallons of gasoline every 38 working days.

"With 164 vans now operating at fourteen Gulf facilities, we save 4,164 gallons of gasoline every working day! Of course, van pooling isn't the only way Gulf conserves energy. We cut fuel consumption of our tank truck fleet almost 13%, and of our eight refineries by 20%, compared to 1972.

"Energy conservation is a tremendous challenge, but we have to meet it if this country is ever to become less dependent on expensive imported oil in the future. It's only reasonable that Gulf, as one of America's leading energy producers, should work just as hard at being one of America's energy savers.

"We put together a how-to-do-it booklet to make it easier for other companies to start van pooling. I'll be glad to send you a copy if you just write to me, Ken Sawicki, at P.O. Box 2001, Houston, Texas 77001."

IN A FUEL-
OBSESSED SOCIETY,
IS IT BLASPHEMY
TO SUGGEST THAT
A CAR SHOULD
BE FUN TO DRIVE?

What with the threat of the as Line'' eternally poised over collective heads, our national occupation with fuel efficiency erfectly understandable.

The question must be ed, however, does meeting demands of the gas pump ot to mention the endless am of safety and anti-ution regulations—mean that are doomed to suffer a eration of terminally boring omobiles?

If one accepts as fact the nal cries of woe emanating n the automotive community, ould seem so.

Yet, if one drives the BMW i, it becomes apparent that is not at all the case.

Indeed, while overcoming se seemingly insurmount-e obstacles, the BMW 320i vides the sort of exhilarating formance enthusiasts have out given up for lost.

## THE THRILL OF ERFORMANCE WITHOUT HE SIN OF GAS GUZZLING.

Even before the words ''gas is'' became a permanent t of the language, small, practical family sedans were not well known for their performance capabilities.

A truth which makes the 320i all the more remarkable.

Take a hair-raising curve and the legendary BMW suspension system—independent on all four wheels—flexes with an uncanny resiliency that makes one feel as if the car were slotted into the roadway.

Press the accelerator and the four-cylinder, 1.8-liter, fuel-injected, overhead cam engine responds in a manner that can only be described as exhilarating, even by pre-pollution control standards.

Yet, the 320i (with 5-speed standard transmission) delivers an impressive $\boxed{25}$ EPA estimated mpg, 36 estimated highway mileage and, based on these figures, an estimated mpg range of $\boxed{383}$ miles and a highway range of 551 miles.

(Naturally our fuel efficiency figures are for comparison purposes only. Your actual mileage and range may vary, depending on speed, weather and trip length. Your actual highway mileage and highway range will most likely be lower.)

## AN INTERIOR ENGINEERED FOR SERIOUS DRIVING.

Perhaps no more succinct an expression of engineering intelligence exists than the interior of the BMW 320i—each facet strategically planned to help prevent driver fatigue.

Vital controls are within easy reach. The tachometer, speedometer and ancillary instruments are well-marked, easy to read and set in a control panel that sweeps out to meet the driver.

Its front seats are designed to hold their occupants firmly in place, and are so thoroughly adjustable that it is all but impossible not to find a comfortable seating position.

All in all, in a time of lowered automotive expectations, amidst increasing mediocrity, the engineers at BMW have actually improved the BMW.

If you'd care to judge for yourself, phone your nearest BMW dealer to arrange a thorough test drive.

**THE ULTIMATE DRIVING MACHINE.**

BMW, MUNICH, GERMANY.

# SOME THOUGHTS ON REACHING EIGHTY

It is only human, I suppose, to give importance to birth dates and decades, and so we are proud to celebrate the eightieth anniversary of the American Museum of Natural History's magazine, *Natural History*.

Most of the articles in this special issue have been selected from the magazine's first half century. They range from starlings to planets, from the discovery of early humans to the failure to discover the Loch Ness monster. With many articles, a postscript brings these ever changing subjects up-to-date.

The authors, too, are a diverse lot, including explorers, a president of the United States, Museum presidents and directors, and Margaret Mead. The illustrations come mainly from the photographic archives of the Museum's library. Some of the articles have been trimmed a bit because even in the good old days authors tended to ramble on, but in order to preserve the historical flavor of the times, we have not changed the style or manner of presentation. Some regular features also appear in the last quarter of the magazine.

Perhaps a magazine, and especially this magazine, should be wary about emphasizing anniversaries. The month after month publication—with each issue tied to the previous one and influencing the next—seems more like a plant cloned from the root of the mother plant. Certainly, *Natural History* of 1980 is genetically related to its first issues of 1900. And the environment of the Museum has greatly influenced both.

Like a successful species, *Natural History* has evolved during its 682 appearances in eighty years. In typical American fashion, it has grown bigger and fatter with age. This issue is the fattest yet. It has also grown more cosmopolitan both in its subjects and its audience. Its distribution and readership have doubled in the past decade—currently nearly two million people read our half million copies. And with age the magazine has become more colorful and prestigious, if the recognition given last year and this year in the National Magazine Awards and the Society of Publication Designers Competition is a criterion.

Fat, prestigious, proud, and eighty. Are these signs of a magazine in its prime (and therefore nearing its dotage)? Not really. Not if the plans for growth, change, and great future issues are considered. This year *Natural History* will increase its frequency from ten to twelve times a year. It will drop its book bonus and separate calendar, but will include the calendar with a fall issue and two months will be special issues. The 1981 calendar, based on artifacts from the Museum's new Hall of Asian Peoples, will contain some of the most beautiful pictures the magazine has ever published.

If it keeps growing, expanding, changing with the times, yet returning to its roots for direction and consistency, *Natural History* should be around for many more lively decades. In 1900, the Museum's second vice president, Henry F. Osborn (later to become one of its greatest presidents), wrote that the magazine should keep members and the public "informed of all that is going on . . . and [of] the diffusion of natural science." That should keep us busy for the next eighty years.

*Alan Ternes, Editor*

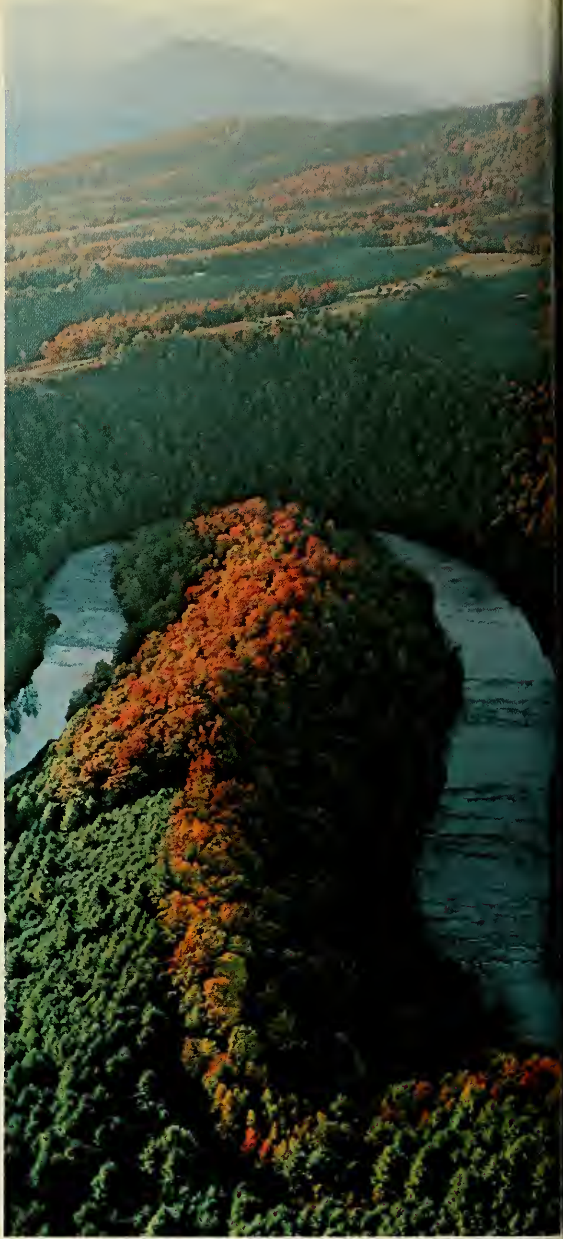
# COME SEE THE STATE THAT KEPT THE WORLD'S SECOND OLDEST RIVER FROM DYING OF UNNATURAL CAUSES.



Its name, ironically, is the New River. It is 500 million years old.

Older than the first, tentative fishes. Older than the trees.

And, not long ago, it almost went the way of the dinosaurs.

Except for North Carolina, the prehistoric river would be just another man-made lake by now.

But today it flows, unchanged, through gentle hills and fertile valleys. As a part of the National Wild and Scenic Rivers System.

North Carolina, you'll begin to notice from the moment you cross its borders, is a state that takes nature seriously.

You can walk in vast mountain forests that have barely changed since the coming of man.

You can stroll beaches where only the crabs and waterfowl are permitted to take up residence.

From the Great Smokies to the Outer Banks, national and state parks and forestlands cover not just hundreds of square miles, but thousands.

You can camp beside a waterfall, catch your breakfast in a clear mountain stream, and never see a sign of civilization. You can go looking for seashells without having to look at high-rise condominiums. You can run the rapids.

Get soaked to the skin. Go to places you'd never see from the window of a car. Do things you've never done, just because you've never done them.

So come. Enjoy. But do us one favor, please. Try to leave North Carolina the way you found it. Because that's exactly what we're trying to do.

*For more information about North Carolina, and a package of free booklets to help you plan your next vacation, write North Carolina Travel, Department 361, Raleigh, North Carolina 27699.*

**NORTH CAROLINA**

# Authors

**Rudolph Martin Anderson** (1876–1961), born in Iowa, became a Canadian citizen and joined the staff of the National Museum of Canada in Ottawa in 1913. From 1920 until his retirement in 1948 he was chief of the Division of Biology. Anderson served as zoologist and chief of the southern party on the Canadian Arctic Expedition of 1913–16, led by Stefansson, and later edited the sixteen-volume *Reports*, detailing the scientific results of that venture.

**Richard E. Byrd** (1888–1957), a naval aviator, was perhaps America's most famous and controversial polar explorer. His claim to have flown over the North Pole in 1926 was later disputed on the ground that his plane was incapable of making the flight within the reported elapsed time. A year later, with three companions, he flew across the Atlantic Ocean. In the late 1920s, Byrd established a base camp in Antarctica, called LITTLE AMERICA, from which he explored the continent. In 1955, he was put in command of all United States antarctic activities.

**Roy Chapman Andrews** (1884–1960) joined the staff of the American Museum in 1906. At the beginning of his career, he specialized in the study of whales and other aquatic mammals. During the First World War, he called the attention of the U.S. Food Administration to the possibility of using whale meat as a food source (it was then being used as fertilizer). As the Museum's assistant curator of mammalogy and, then, as curator-in-chief of the division of Asiatic explorations and research, Andrews led three expeditions: to Tibet, southwest China, and Burma (1916–1917); to northern China and Outer Mongolia (1919); and to central Asia (1921–1930). He served as director of the Museum from 1935 until 1942, when he resigned in order to write. He lectured widely and was the author of numerous books.

**Harold Elmer Anthony** (1891 1970) came to the American Museu in 1911. He was chairman of the D partment of Mammalogy from 1942 t 1958 and deputy director of the Mu seum from 1952 to 1957. Expeditio were a hallmark of his life, and he le collecting trips for the Museum to e ery continent except Australia. He r tired in 1958 and served until 1966 a curator of the Frick Laboratory, a fo sil research laboratory associated wit the Museum. Among the specimens h collected for the Museum were edibl orchids, legless amphibians, a Mon golian mummy, and a barking deer

**Frank M. Chapman** (1864–1945) served with the American Museum fo fifty-four years. He was trained as banker but a voluntary assignmen dealing with the spring migration o birds in 1884 propelled him from a career in banking to one in ornithology He joined the Museum in 1888, jus before the "big blizzard," and became curator of ornithology in 1908. Chapman originated the concept of the "habitat group," which revolutionized the showing of animals in museums. A popular writer on birds, his *Handbook of Birds of Eastern North America* reached three editions in the year it was published, 1895.

# 1980 FORD BRONCO

## A new advance in family 4-wheelers.

Exciting news for 1980: Bronco introduces Twin-Traction Beam, the only truck in its class with independent front suspension. Feel the difference on the road. And off.

Ford's new design Bronco gives you the best estimated mpg of any V-8 4-wheeler. Trim new size outside for easy maneuvering. All-new nterior with more front leg room, improved climate control, new anti-theft features.

Bronco's built tough on a truck chassis, tested tough at Ford's Arizona Proving Ground. Test it at your Ford Dealer. Ask about Ford's corrosion perforation warranty. It's a no-cost 36-month limited warranty that excludes exhaust system components. And ask about Ford's Extended Service Plan, too.

**BEST V-8**
**ESTIMATED MPG**

**15 mpg**
EPA EST.*

Optional 5.0L (302 CID)
V-8 with automatic transmission.

*Compare this estimate with others. Your mileage may differ depending on speed, distance and weather. California excluded.

Built Ford Tough

**Roomy interior** has all-new styling, options like tilt steering wheel, reclining Captain's Chairs up front, AM/FM stereo with cassette or 8-track tape player.

**New Bronco choices** include six roof colors. Above: Landau Tu-Tone with accent tape stripe. At top: Free Wheeling Bronco shown with optional tri-color tape stripe, styled steel wheels, RWL tires, and more.

**Independent front suspension** eases wheels over bumps separately to give a better ride than last year. Helps off-road control.

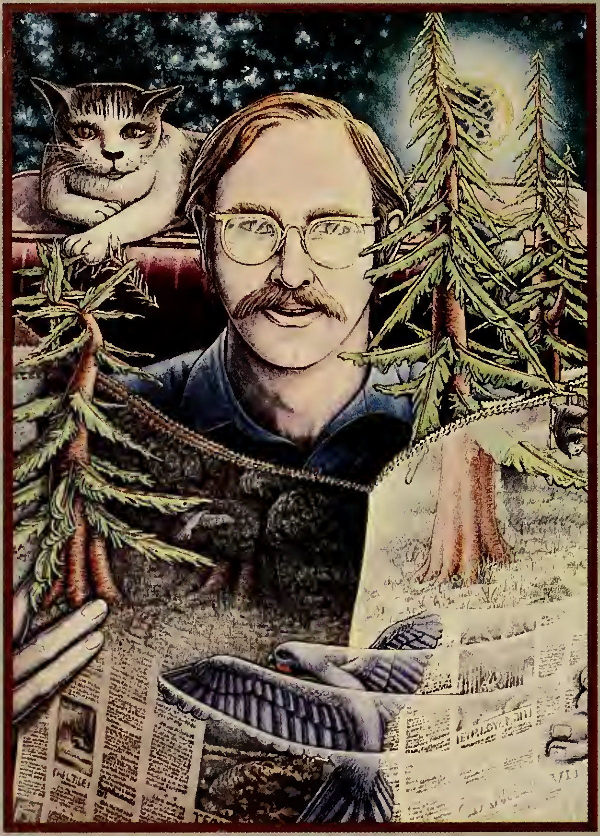
## What do you see when you look at your newspaper?



It depends on your point-of-view.

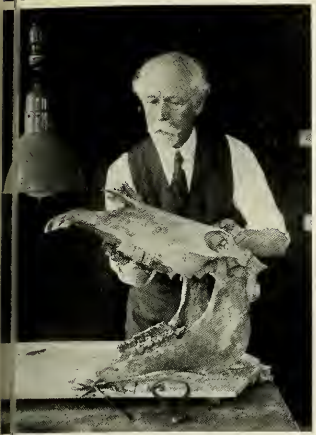
You might see a timely source of useful information, jobs for many people, or the short-lived ghost of a once-proud tree.

We see these things, and more. We see a big part of a business our employees and shareholders depend on. We're one of the world's leading suppliers of paper products.

We also see the trees that stand behind these products, and we strive to manage them in a way that reconciles your viewpoints, so that we can provide satisfactory jobs, products, profits and thriving trees.

If we succeed, everybody wins. Reason enough to try, don't you think?

**Boise Cascade Corporation**
A company worth looking at.



**Samuel H. Chubb** (1863–1949) was dicated to the craft of mounting sletons of horses and other animals i ifelike, active poses. In 1892 he sold h first animal skeleton to the Americ Museum, where he pursued his scial interest up to the time of his ath fifty-seven years later. He was ierviewed for *Natural History* in 123 by A. Katherine Berger, the gazine's assistant editor.

**Theodore D. A. Cockerell** (1866–48), an entomologist, was a prolific ntributor to scientific journals, rticularly on the subject of bees, a elong passion of his. By 1938 ckerell had published 5,840 new mes for species, subspecies, and rieties of bees. From 1888 to 1945 he blished more than 1,200 scientific pers (a few were coauthored). He so developed the red sunflower, a dely known variety, from a single ld plant discovered by his wife.

**Edwin G. Conklin** (1863–1952), professor of biology and chairman of the Department of Biology at Princeton University from 1908 until his retirement in 1933, did important research in embryology and helped establish the field as a discipline in its own right. In addition, he wrote extensively on Darwinism and lectured on the relations between science and ethics. He was a strong supporter in the early 1900s of the young field of experimental biology. Conklin's book review reprinted here is of a work by Thomas Hunt Morgan, one of the pioneer experimental geneticists.

**Raymond A. Dart** (1893–) was a professor of anatomy at the University of the Witwatersrand in Johannesburg, South Africa, in 1925 when he received a fossil skull found by a miner. On examination of the skull, Dart's conclusion was that he had found a new fossil species, *Australopithecus africanus,* intermediate in its characteristics between apes and human beings. Dart retired in 1959 as a professor emeritus and still lives in South Africa; he celebrated his eighty-seventh birthday February 4.

**Lincoln Ellsworth** (1880–1951) was a wealthy engineer, explorer, and adventurer, who financed many expeditions himself. He led the first transarctic air crossing in 1926 and in 1936 was the first to cross Antarctica by air. Twice he financed and accompanied Roald Amundsen, the Norwegian explorer, in polar air explorations. During four expeditions to the Antarctic, Ellsworth claimed a total of 300,000 square miles for the United States.

**Clyde Fisher** (1878–1949) was a member of the scientific staff of the American Museum for twenty-eight years and curator-in-chief of the Hayden Planetarium from its opening in 1935 until his retirement in 1941. He organized the Museum's Department of Astronomy in 1924 and campaigned for ten years to get its planetarium built.

**Amadeus W. Grabau** (1870–1946), for twenty years a professor of paleontology at Columbia University, was a leading figure in both paleontology and geology. He pioneered advances in stratigraphy, set forth the principles of the field of paleoecology, and supported an early theory of continental drift. In 1920 Grabau moved to China, where he spent the rest of his life. He became professor of paleontology at the National University there and chief scientist of the Geological Survey of China.

**William K. Gregory** (1876–1970), an ichthyologist and paleontologist, joined the American Museum in 1899 and retired in 1944. His specialty was the anatomy and dentition of fish and mammals. During the course of his long career at the Museum he served as curator of ichthyology and comparative anatomy and planned and supervised a number of exhibits.

**George Bird Grinnell** (1849–1938) was an American naturalist prominent in conservation movements. In 1886 he organized the first chapter of what later became the National Audubon Society, and in 1896 he helped found the New York Zoological Society.

**David Starr Jordan** (1851–1931) was the first president (in 1891) of Stanford University. He came there from Indiana University, where during six years as president he instituted such innovations as elective courses and a major field of study for students. Jordan's discipline was ichthyology, and he studied fish of the Pacific coast, the Gulf Coast, Florida, Cuba, and the major American rivers. His ideas on speciation, reprinted here, grew out of early field trips in the southern United States.

**William D. Matthew** (1871–1930
curator of vertebrate paleontology a
the American Museum when the art
cle reprinted here was first publishe
spent more than thirty years at th
Museum, starting in 1895 as an assis
tant in the Department of Vertebra
Paleontology. He left in 1927 to be
come curator of the Paleontologica

in the South Pacific and as a com
mentator on contemporary social is
sues.

Some things just naturally go together.

Seagram's V.O.
The symbol of imported luxury. Bottled in Canada.
Enjoy our quality in moderation.
Canadian whisky. A blend of Canada's finest whiskies. 6 years old. 86.8 Proof. Seagram Distillers Co., N.Y.C.

If you have ever taken a luxury sports car through a tight turn, you know the feeling. It's the sense of supreme precision with which this trim, compact camera proclaims its Nikon heritage. A feeling that is borne out by the professional quality pictures the Nikon FE delivers with automatic ease. And one that, unlike other fine things in life, is readily affordable.

*With the Nikon FE,* you can simply focus and shoot... and rely on its Nikon electronics to give you sharp, magnificently exposed photographs, automatically. Or, switch to manual operation and enjoy complete creative control over every exposure, more easily than you ever thought possible.

*Above all,* this is a camera that makes no compromise in its supreme Nikon quality. Stroke the advance lever, and feel the smoothness of precision gearing machined to microscopic tolerances. Press the exposure button, and hear the shutter respond with hushed precision. Look through the bright, silver-coated viewfinder, and see your picture snap into sharp focus with a fingertip touch.

*Know, too,* that the world's greatest photographic system stands behind your Nikon FE. Add the dynamic firepower of motor drive, at up to 3.5 shots a second. Banish darkness with the ingenious automatic thyristor flash. Explore new perspectives through more than 60 Nikkor lenses, the same superb optics chosen by most professionals for their sharpness and color fidelity.

**For the purist:**
**The Nikon FM**
For those who prefer only manual exposure control, the Nikon FM offers the reliable guidance of one-step electronic metering. It's as compact and precisely responsive as the FE and costs even less. At your Nikon dealer.

**Experience a sense of perfection. The Nikon FE.**

**Henry Fairfield Osborn** (1857–1935) became president of the American Museum of Natural History in 1908 and kept that position for twenty-five years, presiding over a period of great growth for the Museum. He came to the Museum from the faculty of Princeton University in 1891. In that year he founded both the Department of Biology at Columbia University and the Department of Vertebrate (then Mammalian) Paleontology at the Museum. Although his original scientific work was in vertebrate paleontology, his interests were wide and included conservation. Osborn developed a comprehensive theory of evolution that few scientists accepted. He fought against the Tennessee antievolution statute that resulted in the famed Scopes monkey trial. And, like some other scientists of his time, including Edwin G. Conklin and David Starr Jordan (also represented in this issue), he had a strong interest in eugenics, the improvement of the human race through selective breeding.

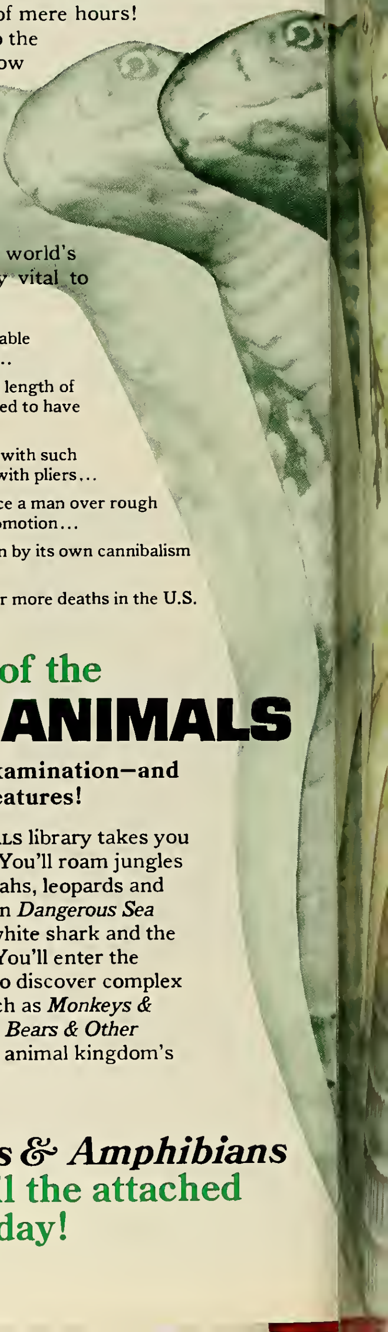
**Chester A. Reeds** (1882–1968) became curator of the Department of Geology and Invertebrate Paleontology of the American Museum in 1925 and served in that capacity until 1938. His association with the Museum first began in 1910, after a brief stint as a lecturer in geology at Bryn Mawr College. Reeds was born in La Cygne, Kansas, and received his Ph.D. from Yale University in 1910. A Fellow of the American Geological Society, he published extensively in his field.

**Theodore Roosevelt** (1858–1919), twenty-sixth president of the United States, had a lifelong interest in natural history. As a conservationist, he was instrumental in reserving millions of acres of land for public ownership. Contributing to his reputation as an outdoorsman is the story of how, on a Mississippi bear hunt, he refused to shoot a bear that had been captured as a trophy for the White House. The incident was popularized in a 1902 newspaper cartoon and inspired the creation of the ever popular Teddy Bear.

**Vilhjalmur Stefansson** (1879–1962), the Canadian explorer and ethnologist, depended for the success of his Arctic expeditions on living off the land according to Eskimo ways. He wrote several books about his explorations, including *My Life with the Eskimo, The Friendly Arctic, Unsolved Mysteries of the Arctic,* and *Discovery.*

**Gilbert L. Wilson** (1869–1930) spent two months of each year, from 1908 to 1918, among the Hidatsa, or Gros Ventre, Indians, gathering information about their culture for the American Museum. He published monographs on the dog and horse culture complexes of this tribe. Wilson looked upon the narrative, and the demonstrations accompanying it, as data, to be set down verbatim. His method was to control the narrators as little as possible, merely holding them to a description of actual personal experiences. At the time of the work reprinted in this issue he was a graduate student in anthropology at the University of Minnesota.

# KING COBRA



The King Cobra...the largest venomous snake on earth. He can deliver more venom than any other snake—enough poison to kill a 10-ton elephant in a matter of mere hours! The unusual sensors in his flicking, forked tongue alert him instantly to the presence of prey. His lethal venom is discharged through short, hollow teeth...while his double-hinged jaw and elastic throat permit him to consume prey much larger than himself.

The King Cobra—deadly, mysterious, unpredictable—is just one of the fascinating creatures you'll meet in *Reptiles & Amphibians*, your introductory volume in the WILD, WILD WORLD OF ANIMALS library—based on the popular TV series from TIME-LIFE TELEVISION.

*Reptiles & Amphibians* will bring you face-to-face with some of the world's most elusive, dangerous, and useful creatures...all in their own way vital to mankind in keeping the balance of nature. You'll discover:

Cuban knight anole is the giant of the genus at 18 inches.

- **Flying Snake of Borneo,** actually capable of "flight" between trees up to *40 yards apart*...
- **Anaconda,** a constrictor which grows to a length of more than 25 feet (one such snake was reported to have devoured a five-foot caiman—whole!)...
- **Gila Monster,** which hangs onto its prey with such tenacity, it sometimes can only be torn loose with pliers...
- **Racer Snake,** which can easily outdistance a man over rough terrain by means of a complex serpentine locomotion...
- **Crocodile,** slowly driven toward extinction by its own cannibalism of its young...and man's greed for its hide.
- **Eastern Diamondback,** responsible for more deaths in the U.S. than all other snakes combined...

## Discover the action-photo excitement of the
## WILD, WILD WORLD OF ANIMALS

**Send for *Reptiles & Amphibians* today for a 10-day free examination—and begin your journey into the lairs of the earth's deadliest creatures!**

The poisonous tropical frog...toxin from his skin can paralyze on contact!

The WILD, WILD WORLD OF ANIMALS library takes you on an incredible photographic safari. You'll roam jungles and plains in *The Cats* to watch cheetahs, leopards and lions. You'll dive to the ocean's floor in *Dangerous Sea Creatures* to see the terrifying great white shark and the needle-sharp teeth of the barracuda. You'll enter the miniature world of *Insects & Spiders* to discover complex social structures. Future volumes such as *Monkeys & Apes, Elephants & Other Land Giants, Bears & Other Carnivores,* introduce you to all of the animal kingdom's astonishing creatures.

# NORTH TO 88 AND THE FIRST CROSSING OF THE POLAR SEA

BY LINCOLN ELLSWORTH

*"When one goes forth a-voyaging*
*He has a tale to tell."*

IT had always been Capt. Roald Amundsen's wish to fly to the North Pole, and there if possible, abandon one plane in order to refuel the other from her, and with the remaining plane go on to Point Barrow, Alaska. Because the interest of us both lay, not in the attainment of the Pole—Peary having already been there—but the exploration of that great million square miles of unknown Polar Basin beyond, we took this into consideration in planning our 1925 flight from Spitzbergen with two aëroplanes.

The story of our flight over the Polar Sea to within 120 nautical miles of the Pole has already been told. Although we didn't reach the Pole, the flight had shown that the meteorological conditions prevailing over the Polar Basin offered no hindrance to its successful exploration by means of the proper kind of aircraft.

After our experience with airplanes we decided to buy an airship, and we went to Italy because Mussolini had one that appeared to fit both our needs and the size of our purse.

The N.1, built to the designs of Col. Umberto Nobile in the Italian State Airship Factory, and christened by us the "Norge," was of semi-rigid construction, 349 feet long and of 20 tons displacement. Her fuel capacity of 7 tons, to run her three 250 horse-power Myback motors, gave her a range of 3500 miles, or about 70 hours, at a speed of 50 miles per hour. Her gas capacity of 660,000 cubic feet was about ⅓ that of R.33.

The "Norge" was equipped with a Marconi wireless direction finder, the tuning-circuit for which was designed to cover a wide band of wave lengths; those used ranged from 900 to 1400 meters. The energy for the specially constructed valve transmitter was delivered from a windmill-driven generator supplying 3000 volts.

There was a delay of several days after the long flight from Italy to Spitzbergen, before the "Norge" was able to proceed on her journey across the Polar Sea. Favorable weather conditions were essential. We needed a clear sky with good visibility, and a favorable wind; also a high barometric pressure and a low temperature. These last two elements influenced greatly the lifting capacity of the dirigible. For each degree Fahrenheit that the temperature went down, the airship gained 80 pounds in lifting capacity, which was increased by 140 pounds for each tenth of an inch added to the barometric pressure.

The keel of the "Norge" looked like a flying storehouse when all was ready for the start at 8.55 o'clock on the morning of May 11, 1926. The equipment included tents, sleeping-bags, skiis, snow-shoes for those who couldn't ski, rifles, shot-guns, ammunition, a hand-sledge—the finest piece of workmanship I ever saw—made by Oskar Wisting on the "Maud," and a canvas boat. Two men among the personnel, Amundsen and Wisting, had the distinction of having been at the South Pole, and now both were en route for the North Pole.

Provisions consisted of pemmican, chocolate, oat biscuits, and dry milk, sufficient to last 16 men two months, with a daily ration of 500 grams for each man.

On the walls of the cabin hung the pictures of Norway's King and Queen, presented to the "Fram" on the expedition to the South Pole in 1910; an image of the Madonna which the Italians had brought with them; and a four-leaf clover given to the ship by Major Scott, who piloted the British airship R. 34 across the Atlantic. In the keel hung the flags of Norway, the United States, and Italy, to be dropped on the North Pole.

To those who made the first crossing of the Polar Sea it will ever be "life's great adventure," for in all human experience never before has man traveled so fast and so far into the realm of the unknown. There is an indefinable something about such an experience, where illusion and reality are so hauntingly intermingled, that ever after it may well color one's whole sentiment of existence.

Two hours after leaving King's Bay we found ourselves over the "pack-ice." What weather! The sun shone brilliantly out of a sky of pure turquoise, and the whalelike shadow that our airship cast beneath us trailed monotonously across a glittering snowfield, unbroken, save where wind and tide had rift the icy surface into cracks and leads of open water. Three white whales darted under the protecting shelf of an ice-floe, and polar bear, frightened at the sight and noise of the weird monster that took to the air instead of the sea, dived into the sheltering leads, sending up columns of spray that reflected the bright sunshine.

As we approached latitude 83½ the snow-crowned peaks of Spitzbergen merged into the deepening blue of the southern sky, losing their identity, and all signs of life vanished. Intermittent fogs rolling beneath us like a great woolen ocean, hid the ice from our view. Approaching 88 we had to rise from 1800 feet to more than 3000 in order to get over it. Latitude 87.44—what memories! The motors were slowed down in commemoration of our sojourn there the year previous, although we were passing the exact spot 50 miles to the eastward.

In this latitude, during the summer months, it is difficult to separate days and nights, for the sun swings

around the horizon at practically the same altitude during the entire twenty-four hours. But our Greenwich chronometer told us we had been out 16½ hours, so the time was really 1.30 A.M., May 12. The fog had completely cleared away and there was no wind. The navigator who had been on his knees at one of the starboard windows since 1.10 with his sextant set on the height and declination the sun should have at the Pole, corresponding to the given date, suddenly announced, "Here we are!" as the sun's image started to cover his sextant bubble. We were over the North Pole! With motors throttled and heads uncovered we descended to within 300 feet of the ice and dropped three flags.

"There is no more evanescent quality in an accomplished fact," says Conrad, "than its wonderfulness." Solicited incessantly by the considerations affecting its fears and desires, the human mind turns naturally away from the marvelous side of events. And it was in the most natural way possible that, after crossing the Pole, we filled our mugs with meat-balls immersed in a liquid of hot grease, from a large thermos cask, and, squatting down anywhere out of the way of trampling feet, devoured the first and only hot meal of our entire voyage from Spitzbergen to Alaska.

With full speed ahead we settled down to the monotony of routine again, heading southward instead of north, with the sun-compass settled for Point Barrow, Alaska, 1500 miles away. Ahead lay the world's biggest unexplored area. What would it reveal, a lost continent, islands, or what? Would we cross safely to tell the world what we had seen? Hour after hour passed, but only the same glittering surface rift by wind and tide into cracks and leads of open water, was here as before crossing our route, in a west-east direction. We reached the "Ice-Pole" at 7 A.M., five and one-half hours later.

This "Ice-Pole," so called because it is the center of the Arctic ice-mass and therefore the most nearly inaccessible spot in the Arctic regions, lies in latitude 86 N. and longitude 157 W. But its inaccessibility was now conquered.

We had covered one half the distance between King's Bay and Point Barrow. Of the seven tons of fuel the ship carried, only about two tons had been consumed. Here, strange to say, we picked up the first sign of life since leaving 83½ (almost 700 miles), one lone Polar bear track. What a challenge! What a mockery to our egotism! Yet there it was, plainly crossing a large ice-floe. Only a Polar bear, but something alive and like ourselves seeking—but what, away out here? Anyway, it was something tangible again. The sense of utter solitude—the illusion of disembodiment—that had taken possession of me, as I seemed to float through the void like a lost soul, beyond the confines of a three-dimensional world, vanished, and in its place sprang eternal hope and the desire to achieve.

Just ahead, so it seemed, lay Alaska, the goal of our dreams. "A little more, yet how far it was; a little less, but what worlds away." But as we approached its coast, fears assailed us; for we ran into the only storm during our entire voyage—fog, wind, and sleet—and for thirty-one hours we battled. Ice coated the aërial wire and froze the windmill driver of our generator, which supplied the electrical energy to operate the transmitter and charge the storage batteries, and all efforts to establish communication with Alaska were of no avail.

Ice-crust formed on the bow of the ship. This was alarming, not only because it loaded her down, but also because it spoiled her trimming. We tried to counteract the effect by moving the fuel from the bow tanks and sending the crew aft. Needless to say, our greatest danger lay in the ice that was torn loose from the sides of the ship by the whirling propellers and thrown against the gas bags. An ice-block of the most fantastic shape settled on the sun compass, stopping the clockwork and putting it out of action for the rest of the flight.

It was a surprise, therefore, to find by observation at 4 A.M., on May 13, that we were in a nearly north-south position on a line striking the Alaskan coast and passing only twenty-one nautical miles west of Point Barrow, because it had been nearly twelve hours since the last longitude observation. At 6.45 A.M., land was sighted ahead on the port bow, and at 7.25 after a voyage lasting 48 hours, we reached the coast. Flat and snow-covered, it was the most desolate looking coast line imaginable, but it was land and that was enough.

As we passed over the coast line the fog became denser and denser, obliging us to go lower and lower in order to be able to see far enough ahead so that we would not run against obstacles. At last, abreast of Cape Beaufort, it became impossible to see any longer, and we rose through fog and cloud into bright sunshine. Heavy layers of fog drifted beneath us, and only now and then through openings in it could we glimpse the barren peaks of the Endicott range, over which we were passing—far too little to enable us to make out our whereabouts.

When we believed ourselves as far south as we could go, we tried to get down underneath the fog and do our best to find the way. We had to nose down to an elevation of only three hundred feet before we could see what lay beneath. We were over drift-ice again. Where were we? Unreal as it may seem, our wireless picked up a strong signal at this moment, which we thought might be Nome but we could not tell for certain, because it was a communication with another station and we couldn't get the signature. But it gave us a position north of Diomede Island and enabled us to set a course for Cape Prince of Wales.

Very soon we were over open water which aroused our suspicions, for we might just as well be on the outside of Bering Strait and, with our course, heading straight for the Aleutian Islands. Getting into sunshine again we were obliged to take our observation from the top of the ship, as the sun at this latitude was so high that it was hidden by the envelope in whichever direction the ship pointed. The observation gave our latitude as 67.30. We then went down through the clouds and found ourselves over land, having passed over the whole of Kotzebue Bay, driven by a northerly gale of more than 70 miles per hour. Heading west to get to the sea again, we heard the Nome wireless, which together with the identification of the coast line, gave us our exact position.

At 3.30 on the morning of May 14, we rounded Cape Prince of Wales, and, tired but happy, brought our airship, coated with a ton of ice, safely to rest at the little trading post of Teller, 91 miles northwest of Nome, after a journey of 3393 miles, lasting seventy-two hours, across the Polar Sea from Europe to America.

---

Amundsen was the first to navigate the Northwest Passage by ship. He did that in 1903–06, about a decade before the flight described here. In 1969, following the discovery of oil in northern Alaska, the S.S. *Manhattan,* an American ice-breaking tanker, became the first commercial ship to sail the Northwest Passage.

# EVERYBODY'S PLAYING FOLLOW THE LEADER.

As you've probably noticed, the Volkswagen Rabbit's imitators are multiplying like, well, rabbits.

But copies are copies.

And while others are busily copying the Rabbit's looks, they're also busily complaining about meeting the U.S. Government's 1985 fuel-economy standards.

Volkswagen meets those economy standards today.

And while debate over passive-safety restraint systems drags on, you can buy a Rabbit "L" with a system that meets the 1984 safety requirements today.

In short, cars that try to look like the Rabbit from afar don't quite make it from anear. But then, why should anyone have thought they would?

Quality always tells. In handling. In performance. In the paintwork. In the way things fit.

Car and Driver said that the Rabbit "has a structure that feels as substantial as a Mosler safe."

So before you consider a car that looks like a Rabbit instead of a car that is a Rabbit, remember one thing:

It's one thing for a plastic surgeon to make Caliope Brattlestreet look like a movie star. But it's something else to know that you have to snuggle up every night with Caliope Brattlestreet.

IN FINE ENGLISH PORCELAIN…

# The Country Year

BY PETER BARRETT

*A collection of twelve beautiful porcelain plates, each portraying the charm and color of the countryside in a different month of the year.*

*Each plate bears an original work of art and is individually decorated with pure 24 karat gold.*

---

**To be issued in limited edition.**

**Offered by direct subscription only, with a further limit of just one collection per applicant.**

**Subscription application valid until April 30, 1980.**

---

The beauty of a mountain stream in autumn, or a country meadow dappled with summer sun, possesses an enchantment that is universal. And it is the rare ability to capture this unique form of visual poetry — the beauty of the ever-changing countryside — that has established the English painter Peter Barrett as one of today's most gifted landscape artists.

And now, for the first time in his career, Peter Barrett has undertaken the task of creating a collection of important new works for issue in a form particularly prized by collectors: a series of twelve beautiful *porcelain plates* portraying the entire panorama of the countryside.

Each of these original works has been commissioned by Franklin Porcelain and created *exclusively* for 'The Country Year' porcelain plate collection. After it is completed, none of these plates will ever be issued again.

***Each plate captures a different setting, a different month of the year***

To encompass all the splendors of the countryside in its changing moods, each plate will depict a totally different setting . . . in a different month of the year.

The April plate, for example, conveys the loveliness of Spring from the perspective of a secluded bluebell bower . . . The spirit of May invites us to follow a quiet country lane . . . August brings us to a golden wheatfield, where swallows swoop low in search of food . . .

Wheatfields in August

The Colors of Autumn in October

No detail, no matter how small, escapes Peter Barrett's eye. Yet, over and above their sheer beauty, these new works accomplish something even *more* extraordinary. Because each plate actually seems to draw the viewer *into* the scene.

***Challenging to create . . . satisfying to own***

By letting elements of his art burst out of the center of the plate and flow to its very rim, Peter Barrett has given these works a unique sense of depth and dimension . . . a feeling of movement and vitality that brings *life* to every scene.

Furthermore, because of the precision of Barrett's art, and the fact that he has used some twenty-five separate colors in every work, this is a collection as challenging to create as it is satisfying to own. Indeed, more than two years has been devoted to its preparation.

To provide full scope for Peter Barrett's artistry and vision, each plate will measure a full nine inches in diameter. The entire collection will be crafted of fine English porcelain, whose traditional richness and vibrancy are exceptionally well suited to dramatizing the subtle colors of his art. And each scene will be framed within a decorative circular border of *pure 24 karat gold.*

***A collection to enhance any room . . . any home***

Each of the twelve beautiful plates in the collection is a superlative work of art in itself. Together they constitute a gallery of fine art that is breathtaking. Displayed upon the wall or shelves of any room, these beautiful plates cannot help but enhance the decor of your home.

But the plates are being made available on a very limited basis. They will be crafted *exclusively for individual subscribers.* And a further limit of just one collection per subscriber will be enforced without exception.

Here in the United States, the collection will be issued in a single edition, available *by direct subscription only* — and only from Franklin Porcelain. One plate will be issued every other month, and the issue price is just $55 for each plate and individual wall hanger.

Because of the international interest in Peter Barrett's art, a second edition will be made available overseas, with equally stringent limitations. In the tradition of the finest porcelain, the collection will be available only until the end of 1980, at which time the subscription rolls will be permanently closed. To enter *your* subscription, you need send no money now. But the application below must be mailed by April 30, 1980.

OUR PROMISE TO YOU: Franklin Porcelain takes pride in the excellence of its limited edition works of art. Therefore you may return any plate in this collection, for any reason, within 30 days after it is sent to you and receive a full refund or credit.

SUBSCRIPTION APPLICATION

## The Country Year

***Valid only until April 30, 1980.***
***Further limit: One collection per applicant.***

Franklin Porcelain
Franklin Center, Pennsylvania 19091

Please enter my subscription for Peter Barrett's 'The Country Year' — consisting of twelve plates to be crafted for me in fine English porcelain.

I need send no money now. The plates are to be sent to me at the rate of one every other month beginning in June 1980. I will be billed for each plate in two equal monthly installments of $27.50*, with the first payment due in advance of shipment. I understand that I may return any plate within 30 days after it is sent to me, and receive a full refund or credit.

**Plus my state sales tax*

## Six-mode exposure control. System versatility. Newer electronics for wider applications.

SHUTTER PRIORITY AE
PROGRAMMED AE
ELECTRONIC FLASH AE
MANUAL
STOPPED-DOWN AE
APERTURE PRIORITY AE

The incredible Canon A-1. It's on the cutting edge of technology, with state-of-the-art electronics and computerized operation.

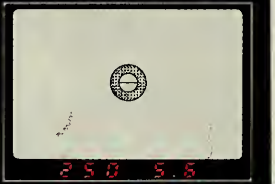
Yet, although the way we build it is complex, the way you use it is the ultimate in simplicity. If push-button-easy fine photography is what you're after, the A-1 can give it to you six ways.

1 Shutter-Priority automation: You pick the speed to freeze or blur action or prevent camera shake, the A-1 picks the perfect aperture automatically.

2 Aperture-Priority automation: Select the aperture you want for a soft background or total overall sharpness, the A-1 will give you the speed that's correct.

3 Programmed automation: On the A-1, this unique exposure mode picks both aperture and speed in ideal combinations depending on the light. You don't have to set *anything.*

4 Stopped-Down automation: This mode lets you get automatic exposure with any lens or accessory you can mount on the camera. Great for astrophotography, photomicrography, close-ups.

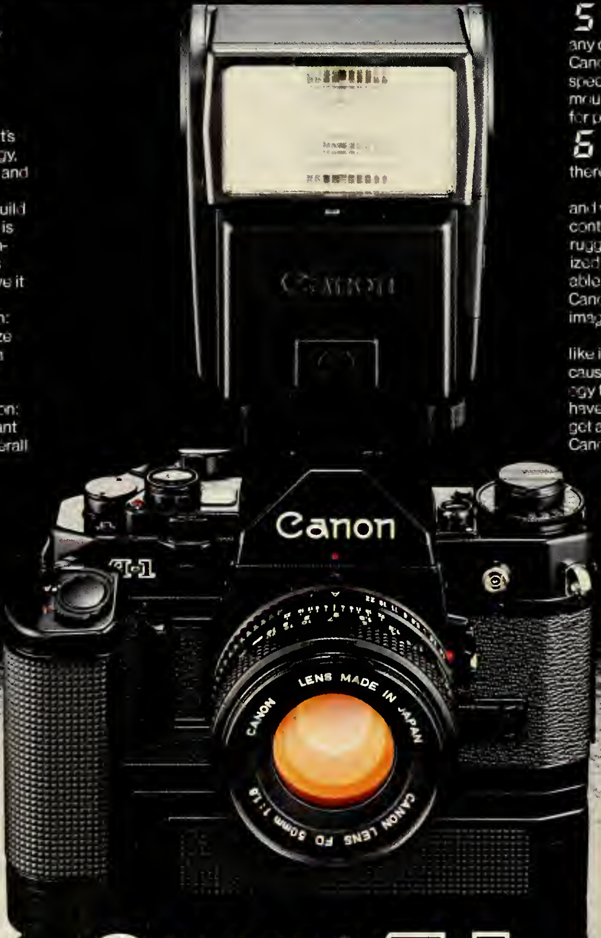


5 Flash automation: The A-1 has the easiest electronic flash of any camera of its type. With special Canon flash units, your aperture and speed are set automatically. Just mount the flash, turn it on and shoot for perfect exposures every time.

6 For any type of photography that's not already covered, there's manual.

There's more. Digital control and viewfinder display. Versatile control features. Accessories like a rugged motor drive, compact motorized film winder and interchangeable date/data back. Plus forty Canon FD lenses for unsurpassed image quality and scope.

You won't find another camera like it on the face of the earth. Because only Canon has the technology to make it. Luckily, you don't have to go to the ends of the earth to get an A-1. Only as far as your local Canon dealer.



Canon A-1

So advanced, it's simple.

# THE HAYDEN PLANETARIUM

The New Addition to the American Museum Which Will Contain the Latest Example of the Most Wonderful Device Ever Developed for Setting Forth Realistically and Impressively the Motions of the Heavenly Bodies

By CLYDE FISHER

WHY did not somebody teach me the constellations, and make me at home in the starry heavens which are always overhead and which I don't half know to this day?"

There will soon be no excuse for those living in the metropolitan district of New York to utter this plaint of Carlyle's, for in spite of smoke, haze, clouds, and the glare of artificial lights, they will have opportunity to become familiar with the night sky, thanks to the new Hayden Planetarium which is coming to the American Museum of Natural History. This realistic representation of the sky is evidently more important to the city dweller than to the suburbanite, since the case of the former is further complicated by the fact that a great portion of the sky is hidden by the ever-present tall buildings.

Devices to show the movements of the planets and our moon in relation to the sun have been constructed since the early days of Copernican astronomy, and no doubt previous to the announcement of the sun-centered theory of our solar system, there were devices to illustrate Ptolemy's earth-centered system. As early as the latter half of the Sixteenth Century, the great Dutch astronomer, Huygens, and the great Danish astronomer, Roemer, built a planetarium to represent the solar system, as it was then known, according to the new Copernican theory, and doubtless this invention had much to do with the general acceptance of the sun-centered notion of our family of worlds.

After the general acceptance of the Copernican theory of astronomy a great variety of instruments was made for the purpose of showing the relative motions of the then known bodies in our solar system—many of them crude, but for the most part very helpful. Some were limited to the earth and sun and moon, others just to the earth and the moon, and still others to the sun and all the known planets and satellites.

One of the most interesting and complicated of these early instruments was built in England for Charles Boyle, the fourth Earl of Orrery, and this one gave us a new word for our dictionaries. The word "orrery" has come to be applied to this type of planetarium.

The most famous orrery or planetarium of this type to be made in America was devised and built by the "Father of American Astronomy," David Rittenhouse of Philadelphia. It is one of the most highly prized of the historical astronomical instruments in the Franklin Institute in Philadelphia, where it may now be seen.

Probably the largest, and certainly one of the best of these old-fashioned Copernican planetariums ever made is installed in the world-famous Deutsches Museum in Munich.

These planetariums or orreries consisted of a series of globes to represent the various bodies of our solar system, each revolving globe supported by a metal rod, the whole system of sun and planets and satellites being connected and propelled by gears so that their relative motions were approximated. Ever since their first appearance, these devices have had and still have great value in teaching, the three-dimensional mechanism capable of simulating the motions of the heavenly bodies being incomparably more effective than flat pictures or pages of printed text.

In these mechanisms just described the observer is outside looking on—a condition that has been improved by placing the model of the solar system inside a spherical glass globe, upon the outside of which is represented the constellations with their principal stars and also the Milky Way—a transparent celestial sphere, certainly an improvement over the usual opaque celestial globe. Examples of this type are the "Astrophane," made by Mr. O. J. Russert, and the small Copernican planetarium just inside the entrance to the Fels Planetarium, made by Max Sendtner of Munich.

The next step in the evolution of the planetarium seems to be the model of the celestial sphere with the audience inside. This type has been developed in at least three different countries. In 1758 Roger Long, Lowndes Professor of Astronomy at Cambridge, built one at Pembroke College. The globe was eighteen feet in diameter and seated thirty persons. The only one of these that the writer has seen is in the Museum of the Chicago Academy of Sciences in Lincoln Park, built before 1913 by Dr. W. W. Atwood. It is known as the Atwood Celestial Sphere. It consists of a hollow metal sphere in which the most conspicuous stars of the sky are shown by lights outside of small, round holes through the sphere. The small audience is seated inside the globe, while the latter revolves as the real sky seems to do. In all of these devices heretofore described, so many astronomical bodies and so many movements and relations have been omitted that they are evidently inadequate.

Late in 1924 there appeared something new under the sun, an apparatus that shows every object in the sky that is visible to the unaided eye, and in a most realistic manner. The rising and setting of the sun, moon, and

**HABAND** Direct by U.S. Mail Since 1925

stars are represented just as they occur in nature, due to the rotation of the earth on its axis. The moon goes through its phases. The planets are shown as wanderers among the stars, their direct eastward and their retrograde westward motions being represented with great accuracy. Even the precession of the equinoxes, together with the swinging of the celestial pole around a circle, which in the sky takes 26,000 years, is shown by this apparatus.

In this new projection planetarium everything is shown on the inside of a dome by projection of light from a central apparatus. The optimum size for this inverted bowl is from sixty-five to seventy-five feet in diameter. This hemispherical dome, which is white inside, becomes our artificial sky, and since there are no pillars or posts to intercept the light, the illusion of the depth of space is perfect. One feels that he has been suddenly transported outside under a clear night sky. The realistic appearance is beyond belief.

The projection apparatus, which is located on the floor in the center of the dome, is a bizarre-looking instrument some twelve feet high, resembling a huge dumb-bell with a long bar between the globular ends. The globes at either end of the instrument are for the projection of the fixed stars, one globe being for the northern and the other for the southern hemisphere of the sky. Each globe consists of sixteen stereopticons pointing in all directions with one central lamp. The lantern slides or diapositives are not square or rectangular, but are so shaped that their images fit together like the cells of a honey-comb, thus making a complete picture of the starry heavens without overlapping and without gaps.

The representation of the fixed stars, including the Milky Way, is a comparatively simple part of the performance of the instrument, and yet it is certainly the most impressive. It matters not whether the audience be made up of children or adults, or professional people or laymen, the emotional experience is always the same. When the light is gradually diminished, bringing on the darkness of night in the dome, and the stars are "turned on," the audience gasps audibly in surprise at the breath-taking beauty of it. No one is prepared for anything so realistic and so dramatic.

The names of the constellations may be shown on this artificial sky by means of a special set of projectors. The advantage of this over outdoor star-gazing in learning the constellations is obvious. With an optical pointer, or flashlight showing an arrow-shaped light, the lecturer can point out any star, planet, or other body in the sky. It is evident that an ordinary fish-pole pointer, even with a tiny light at the tip, would be precluded by the large size of the dome.

In the bar of the dumb-bell between the globular assemblages of stereopticons showing the stars, are seven special projectors, one for each of the five planets visible to the unaided eye from the earth and one each for the sun and moon.

The whole apparatus has several different speeds, all of which are many times faster than the real motions. This makes it possible to condense a long astronomical story into a short time, and with increase rather than loss of drama, so that a child or a grown-up, who has not stopped learning, can get a clear undertstanding in a few minutes of the seemingly intricate though actually simple workings of the heavenly bodies.

With the projection planetarium, one can change his latitude at will. He can go to the Land of the Midnight Sun or to the North Pole, and observe the apparent movements of the sun and moon and stars there; or he can go to the equator, or to southern latitudes and see the Magellanic Clouds, the nearest fixed star visible to the unaided eye, and the romantic Southern Cross.

With the projection planetarium one can go backward or forward in time. He can set the instrument back say 2000 years and note with accuracy the configuration of the planets among the stars at that time; or he can set it back 5000 years, say to 3000 B. C. when Alpha Draconis, the brightest star in the constellation, The Dragon, was our North Star; or he can set it forward say 12,000 years when Vega will be our North Star, and the Southern Cross will be visible from the latitude of New York.

Dr. Philip Fox, formerly professor of astronomy and director of the Dearborn Observatory at Northwestern University, brought the first Projection Planetarium to America and introduced it to our people. Thanks to the generosity of Mr. Max Adler, it has been established in Chicago in conjunction with the best astronomical museum in America, and Doctor Fox is director.

GERMANY is Wunderbar!
Wundercastles

Wundervillages

Wundercities

The Germans have a word for wonderful—it's wunderbar! Wunderbar is the kind of time you'll have in romantic Germany. Wundervalues are what you'll find—more of everything for your money. You'll enjoy wundercastles, cathedrals, landscapes, medieval towns and cosmopolitan cities, quaint country inns and modern hotels, festivals, wunderfood and wunderwine. The Germans are friendly, and most speak English, so travelling by train, plane or car, or taking a cruise on the Rhine, is a delight. Whether you're on vacation or business, a first-timer or a repeat traveller, ask your travel agent to include a visit to Germany in your next European itinerary. Germany is wunderbar!

GERMANY. You'll find a whole lot more than you think.

# ART, REAL ESTATE, GOLD. AND VOLVOS?

There are still a few investments left today that are worth making. And these three people know them when they see them. That's why they all own Volvos.

They not only consider Volvo a safe car to be in; they also consider it a safe place to put their money. Maybe that's because over the last two years the dollar invested in a Volvo has held its value better than the dollar in your pocket.*

Of course if you're shrewd enough to invest in a Volvo, it's unlikely you'll want to turn it over quickly. Because a Volvo is made to last a long time. (The life expectancy of a Volvo is now up to 17.9 years in Sweden.)

And with the money you might save by not buying a new car every few years, you can make another investment as worthwhile as your Volvo. Like art, real estate or gold.

**VOLVO**
A car you can believe in.

---

*Based on a comparison between the consumer price index for the first 11 months of 1977 vs. 1979 and depreciation of a 2-year-old Volvo.* © 1980 VOLVO OF AMERICA CORPORATION

Made possible by the generosity of Mr. Samuel Fels, the second American projection planetarium has been installed in the Franklin Institute in Philadelphia, where it was opened last November. Mr. James Stokley, formerly of Science Service, is director.

The third American projection planetarium is soon to be installed in a building nearing completion in Griffith Park, Los Angeles. It now seems quite certain that New York City will have the fourth American projection planetarium.

The educational value of the projection planetarium is now widely recognized.

With Dr. Oskar von Miller, director emeritus of the Deutsches Museum in Munich, and with Mr. Waldemar Kaempffert, science editor of the *New York Times* and former director of the Museum of Science and Industry in Chicago, we believe that a combination of the Projection Planetarium and a large Copernican Planetarium, similar to the one in the Deutsches Museum, will make an ideal teaching unit, and in accordance with this belief we have planned to install both types of planetarium in our new building.

In the planetarium building, besides the projection planetarium, which is obviously the chief attraction, and the large Copernican planetarium on the floor below, which will be immensely valuable in bridging the conception of the apparent and real motions of the heavenly bodies, there will be many accessory exhibits planned to make the whole astronomical hall a complete and well balanced institution for stirring the imagination and enlightening the mind.

Among these will be the great collection of meteorites belonging to the American Museum. This collection consists of several thousand specimens, representing a few hundred falls. Among them are three brought from Cape York, Greenland, by Peary —one of these, the Ahnighito, weighing 36½ tons, being the largest meteorite in any museum in the world. There is also the famous Willamette meteorite, weighing 15½ tons, which fell near Portland, Oregon, and which has the unusual deep pits developed after its fall. Several specimens, one weighing a few hundred pounds, have come from the vicinity of Meteor Crater in Arizona.

In short, this is one of the most spectacular collections of meteorites in the world, and it will be installed on the main floor of the planetarium building just outside the Copernican planetarium. Up to the time when Kirchhoff made the principles of spectroscopy available, meteorites furnished our only direct and positive evidence of the constitution of any of the heavenly bodies outside of the earth.

Large transparencies made from the finest astronomical photographs in the world will be shown on the walls of the ambulatory around the Projection planetarium dome on the second floor, and on the walls of the first floor around the Copernican planetarium.

Sundials of several types, dial-rings, astrolabes, compasses, hour-glasses, replicas of Galileo's telescopes, and various instruments of historic interest in astronomy will be shown in well lighted cases.

A coelostat, a spectroscope, and a spectroheliocope, all functioning on clear days, so that the results can be observed by visitors, are included in the plans.

A Ptolemic planetarium, three or four feet in diameter, illustrating the old earth-centered theory of astronomy, epicycles and all, enclosed in a spherical glass globe, with a crank that may be turned by visitors, is included.

A Foucault pendulum to show the rotation of the earth on its axis, and a vortex of water to illustrate the same phenomenon are contemplated.

The modern trend in the interest in astronomy will be shown, not only by transparencies from some of the newer photographs of spiral nebulae or galaxies, but also by a model of a galaxy, and a model to show something of what is known about the distribution of the nearer stars in our own Milky Way Galaxy.

All of the astronomical paintings by Mr. Howard Russell Butler, which are now shown in the Pro-Astronomic Hall, as Professor Henry Fairfield Osborn affectionately referred to it, will be reinstalled in the new planetarium building. These include the famous triptych of eclipses (1918, 1923, and 1925), and we hope to add Mr. Butler's fourth picture of a total eclipse of the sun, that of 1932. These are, without much doubt, the finest oil paintings of eclipses ever made. Perhaps as high praise could be given to Mr. Butler's two paintings of Mars, as well as to his other paintings in the hall.

On the outer wall surrounding the Copernican planetarium, on the first floor, there is planned a zonal oil painting representing the zodiac, that belt in the heavens in which the planets are found. This painting will show the mythological figures of the signs of the zodiac and the principal stars of the zodiacal constellations.

To greet the eyes of visitors as they first enter the building, there is under consideration a large decorative painting in oil, in three panels, illustrating American Indian astronomical mythology. Although primarily from the Blackfeet, the myths selected are those of rather wide distribution with little variation among the various tribes of North America. The left panel shows the Northern Lights of Aurora Borealis in the form of an arch in all the delicate colors, in which may be dimly seen the figures of the White Men of the North dancing around their campfires. The central panel shows the sun-

Smaller can be better, as the new full-power Nikon Roof Prism Compact Binoculars clearly demonstrate. Pocket-size slim and just 7-1/2 ounces light, they outperform many bigger and heavier binoculars in sharp, bright, distortion-free viewing. You see the entire scene, even while wearing glasses. And, most important, they're so precisely engineered that you can view for extended periods, without strain or discomfort. Available in all-purpose 6x, 7x and 8x models. See the difference Nikon quality makes, at Nikon camera dealers and selected optical departments. Or write to Nikon Inc., Dept. N-26, Garden City, New York 11530. Subsidiary/Ehrenreich Photo-Optical Industries, Inc. EPI

NIKON ROOF PRISM COMPACT BINOCULARS

Nikon: Official 35mm Camera. 1980 Summer Olympic Games

god on a brilliant yellow background, the moon-goddess on a paler background, while in the upper right may be seen the Pleiades as conceived by the Indians, and in the upper left the Big Dipper and the North Star. These corner representations, with the Milky Way or Sky Trail between them, are shown in silver on a background of deep blue. In the lower left corner is represented the story of the creation of the earth by the Old Man. On the right panel is seen a symbolic Thunder-bird in the clouds with the conventionalized zigzag lightning striking from the cloud to the earth.

The planetarium building has been made possible by a loan from the Reconstruction Finance Corporation, while the instruments, both the projection planetarium and the Copernican planetarium, are the gift of Mr. Charles Hayden of New York City, for whose generosity a multitude of persons will be sincerely grateful.

Many of Dr. Fisher's plans had been realized by the time the Hayden Planetarium opened to the public October 3, 1935. The projection and Copernican planetariums were in place, wall transparencies and Butler paintings were on display, meteorites lined the walls, and the American Indian allegorical painting greeted the visitor at the entrance. But much has changed in the forty-five years the Planetarium has been serving the public.

The Ahnighito meteorite, which was brought from Cape York, Greenland, by Admiral Peary at the turn of the century, was displayed in the Planetarium from its beginning and was then mounted on a Toledo scale in the 1950s. In September 1979 it was removed to the American Museum's Arthur Ross Hall of Meteorites (scheduled to open in the fall of 1980). The zodiac mural in the Copernican Room has been covered by twenty-two projection screens in what is now called the Guggenheim Space Theater. The Butler eclipse triptych is behind a wall in IBM's Astronomia, and another wall covers the allegorical painting. No Foucault Pendulum was ever hung here, but a collection of sundials and old instruments, the bequest of Miss Susan D. Bliss, is still displayed in lighted wall cases.

A new wing added in 1973, courtesy of the Richard S. Perkin Foundation, houses our research library, as well as the Hall of the Sun, which was funded by the Billy Rose Foundation. The Sky Shows feature our third Zeiss projection planetarium: the first was replaced in 1960; the second in 1969, helped by the Hayden Foundation.

And we are approaching an attendance figure of 23 million visitors.

We think Dr. Fisher would be pleased.

If you will join now for a trial period and take only 3 more books—at handsome discounts—over the next 12 months.

(Publishers' Prices shown)

**44955. THE ENCYCLOPEDIA OF MUSHROOMS.** *Dickinson and Lucas.* Beautifully illustrated, outsize reference relates history and biology of over 450 varieties of fungi. Over 400 full-color photographs. $25.00

**33005. THE AMERICAN WALK BOOK.** *Jean Craighead George.* An illustrated guide to the country's major historic and natural walking trails. $13.95

**44930-2. THE ENCYCLOPAEDIA OF IGNORANCE.** *Edited by Duncan and Weston-Smith.* Fascinating encyclopedic exploration of the frontiers of scientific research ranging from evolution to black holes. *Counts as 2 of your 3 books.* $30.00

**41510-2. THE DANCE, ART, AND RITUAL OF AFRICA.** *Michel Huet, et al.* A spectacular, outsize volume which records the pageants and rituals of Africa in more than 250 magnificent photographs. *Counts as 2 of your 3 books.* $35.00

**69328. PLANETS AND MOONS/STARS AND NEBULAS.** *William J. Kaufmann III.* A wide-ranging examination of the solar system, the planets, asteroids, meteors, comets, *plus* a down-to-earth look at stellar mechanics, star birth and death, radio signals in space, black holes, pulsars, neutron stars. *The 2 count as one book.* $26.00

**85863. VIKING: Hammer of the North.** *Magnusson and Forman.* Beautifully illustrated study of the Age of the Vikings, AD 800 to 1100. Outsized. With 120 full-color photos. $14.95

**87890-2. WORLD PREHISTORY IN NEW PERSPECTIVE.** *Grahame Clarke.* Enormous, global survey of *all* civilizations from the first palaeolithic gatherings to the Aztecs. *Counts as 2 of your 3 books.* $29.95

**79975. THE SPOTTER'S GUIDES TO BIRDS, TREES, WILDFLOWERS, ROCKS & MINERALS, SHELLS, AND THE NIGHT SKY.** Six compact field guides, each illustrated in full color with simple, expert text offering practical advice on finding and identifying various species. $23.70

**62915. MONUMENTS OF CIVILIZATION: Ancient Cambodia.** *Mazzeo and Antonini.* Over 100 color photographs. Oversized volume. $25.00

**62700. MIND AND SUPERMIND.** *Edited by Albert Rosenfeld.* Reports on the mechanism of memory, pacemakers for the brain, therapeutic use of megavitamins, and much more. $8.95

**77570. THE SECRET OF ATLANTIS.** *Otto Muck.* A dramatic re-creation of the life and death of Atlantis, which as Muck postulates, was destroyed in the course of a single day by a cosmic explosion of unparalleled proportions. $12.50

**87193. THE WILD CATS.** *Edward R. Ricciuti.* A global, spectacularly illustrated tour of the world of lions, tigers, cheetahs, cougars, lynxes, jaguars and their smaller kin. Over 150 full-color and black-and-white photos. $24.95

**63350. MYSTERIES OF THE MEXICAN PYRAMIDS.** *Peter Tompkins.* Stunning array of 500 photos, drawings and maps. $20.00

**55001. ILLUSTRATED ENCYCLOPEDIA OF ASTRONOMY AND SPACE.** *2nd Ed.* $17.95

**37391-2. THE CELTIC WORLD.** *Barry Cunliffe.* Superb archaeological-historical survey of the Celtic culture. *Counts as 2 of your 3 books.* $39.95

**35506. BACKPACKING EQUIPMENT BUYER'S GUIDE/WALKING SOFTLY IN THE WILDERNESS: The Sierra Club Guide to Backpacking/SIMPLE FOODS FOR THE PACK.** *Softcover. The 3 count as one book.* $19.85

**37353. CATALOGUE OF THE UNIVERSE.** *Paul Murdin, et al.* Three-volumes-in-one: an atlas, encyclopedia, and book of descriptive astronomy. $15.95

**32900-2. AMERICAN RIVERS.** *Bill Thomas.* An exciting textual and magnificent photographical exploration. *Counts as 2 of your 3 books.* $30.00

**63845. THE NATURAL HISTORY OF THE WHALE.** *L. Harrison Matthews.* Presents the latest scientific discoveries about the physiology, behavior, and chances for survival of the whale. 12 pages of photos. $19.95

**61610. MAYA: The Riddle and Rediscovery of a Lost Civilization.** *Charles Gallenkamp.* $15.95

**82771. TEMPLES, TOMBS AND HIEROGLYPHS/RED LAND, BLACK LAND.** 2 excellent introductions to the complex and fascinating subject of Egyptian history. *The 2 count as one book.* $25.90

**77579-2. SECRETS OF THE ICE AGE/THE CAVE ARTISTS.** Vividly re-creates the life, environment and habits of Upper Paleolithic man. *Plus,* explores the craft, styles and meaning of prehistoric cave art. Both books beautifully illustrated. *Counts as 2 of your 3 books.* $31.90

**47210. THE EXPLODING UNIVERSE.** *Nigel Henbest.* Spectacularly illustrated, wide-ranging guide explores everything from the quarks and leptons from which the cosmos is built to the latest discoveries in stellar mechanics and planetary composition. $19.95

**43953-2. THE EGYPT STORY: Its Art, Its Monuments, Its People, Its History.** *Maroon and Newby.* Outsized volume celebrates the timeless splendor of Egypt past and present—in 200 striking full-color photographs and sparkling text. *Counts as 2 of your 3 books.* $39.95

# THE ORDEAL OF GETTING CIVILIZED

Troubles of an Indian Treading the White Man's Path

BY GILBERT L. WILSON

THE old Indian was wending his way upward to his cabin, but stopped halfway up the hill. He was too far away for us to see his features, as he stood gazing earnestly into the evening shadows where they fell on the rolling Missouri; then he turned again toward his cabin.

The young reservation schoolmaster laughed.

"Old Wolf-eye," he said, "I guess he is thinking of other days. He often comes out in the evening and stands gazing at the river. He finds it hard to live like a white man, but he is making a plucky try at it."

"Making any progress?" I asked.

"More than I would make if I were an old buck like him. He's been out in twelve war parties and lifted a half dozen scalps. He walks the white man's way now —has a small trading store beside his cabin; and with a few cattle and horses, and a potato field, and corn, he manages to get out a pretty fair living."

"Does he know English?"

"No, can't speak it anyway. He attended the reservation school for a time, after he was thirty years old, and learned to figure and spell easy words, so he can keep accounts in his trading store; but he has to have an interpreter if a white man comes in. Old Wolf-eye isn't a bad fellow, honest as pure gold."

"Good qualities," I said.

"They certainly are; and Wolf-eye isn't above learning yet, if he is old. Last winter he let his squaw go down to the woods every Monday and cut the week's wood. In the evening the old buck went down with his pony and sledge and hauled the wood home. I told him that wasn't a white man's way; that our women didn't cut the wood; men did that. He was much surprised. 'Indian women always chopped wood in old times,' he said. 'I thought white women did.' The next week old Wolf-eye went to the woods with his ax, and in the evening his squaw brought down his horse and sledge. I guess Wolf-eye isn't as good an ax man as his squaw, for his load was smaller." And the schoolmaster chuckled.

I had wondered what would be the trials of an Indian getting adjusted to civilized life and it struck me that here I had a real find, a native of the old school, who could make clear to me the difficulties a barbarian must experience in treading the white man's path. I determined to seek out Wolf-eye.

The evening of the next day found me with my interpreter, Wolf-eye's nephew, in the old Indian's cabin. The sickly glow of a kerosene lamp half-lighted the room. Wolf-eye sat rather back in the shadows, but his face was toward the light and showed heavy but regular features, with full lips, wide cheek bones, and kindly eyes. He wore a calico shirt outside his overalls; on his feet were moccasins. He was smoking a long-stemmed pipe of redstone. Evidently he was expecting us. A comb lay on the table and his hair, untinged by gray, was newly kempt. Indian-like, Wolf-eye let me begin the conversation.

"You Indians don't show your age," I began diplomatically. "I think you are older than I, but your hair is black as a raven; mine is quite gray."

His answer rather startled me.

"I wish my hair was gray. Then I would be a white man."

"But why would you want to be a white man?"

"Because then I could learn more about this world. I can speak very little English; and there are not more than 500 people to whom I can speak in my own language. What can I learn of them? I know a big war has just ended in Europe. What caused that war? I want to *know* things." The interpreter's English was broken, but I have put his words into intelligible idiom.

"But Wolf-eye," I said, "at least you can live like a white man even if you are not white."

"That is not an easy path for an Indian to walk. Indian ways are not white man's ways, and one cannot refuse to keep to the customs of his tribe. In olden days, we Indians held our foods almost in common. When one family ate, all ate. When one family starved, all were starving. We could not do otherwise. There were few families in the tribe which had not more than once been saved from starvation by food stores of others, especially in winter.

"We do not live so close to starvation now, but we find it hard to forget our old customs. A young couple, just home from the white man's school, are eager to raise wheat and build a good house. In the fall, they gather in their crops and store up potatoes, beans, and dried meat for winter. Then their relatives come to visit them, and stay until all their food stores are gone. I do not think white people do that.

"It is the same if we try to raise stock. Our agent tells us that we ought to raise hogs. My son bought a pig to raise. He built a pen for that pig, and fed it much corn; and he subscribed one dollar for an agricultural paper, to learn how to raise that pig. In the paper he read that he should let the pig out every afternoon for fresh air. So my son bought an alarm clock for two dollars, and set the alarm every day for four o'clock, so he would re-

# Great ideas last forever

Great inventions have the power to forever change the past.

Victor Hasselblad changed the face of photography forever with the invention of the Hasselblad fully interchangeable camera system.

Never before and never since has there been a camera system to equal the Hasselblad–the *standard* of versatility and quality around the world. That's why Hasselblad is the overwhelming choice of professionals in every area of photography, from fashion to photo-journalism.

At the heart of the Hasselblad System is the 500C/M, with its interchangeable lenses, film magazines, viewfinders and film winder. The possibilities for adapting this basic camera to your own purposes are limitless: 22 different lenses, 7 film magazines, 8 viewfinders, 3 winding devices, 4 focusing screens, and a vast array of specialized accessories.

The Hasselblad 500C/M is easily held in the palm of your hand, yet it gives you the quality advantage of its large $2^1/_4 \times 2^1/_4$ negative size.

The Hasselblad System has made a profound contribution to photography. It could make a profound difference to you. For a luxurious folder, write to:

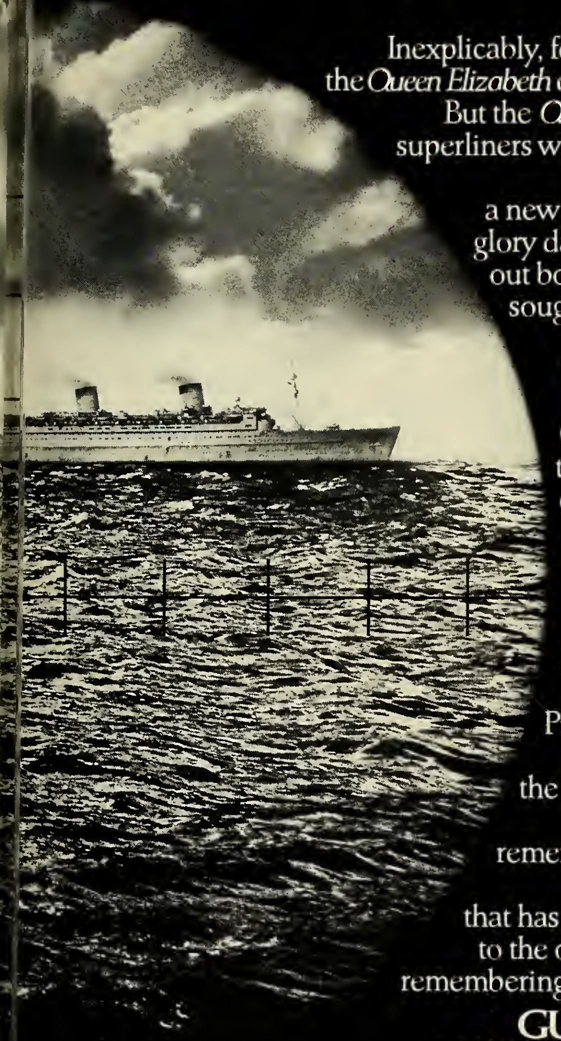
A U-BOAT CAPTAIN WILL NEVER FORGET THE DAY GOD SAVED THE QUEEN.



Inexplicably, four torpedoes Capt. Horst Kessler fired at the *Queen Elizabeth* on that November day in 1942 missed.

But the *Queen* and all but one of the North Atlantic superliners were doomed by time and change.

*The Superliners: Twilight of an Era,* a new National Geographic Special, recalls the glory days of these magnificent ships by seeking out both those who loved them and those who sought to destroy them.

This evocative hour, produced by the National Geographic Society and WQED/Pittsburgh with a grant from Gulf Oil Corporation, shows the ships as they really were: Floating palaces in peace, crowded troop carriers in war, and always at the mercy of the North Atlantic.

Five years ago, Gulf made a commitment with the National Geographic Society and the Public Broadcasting Service to American-made Public Television. Together, we've set Public Television viewing records.

The documentaries are consistently the highest-rated specials on PBS.

For an hour of discovery television, remember the first Monday of April.

And enjoy great television that has sent film crews around the world, diving to the ocean's depths, exploring unknowns, and remembering a passing era.

UNSPOILED.

There are few places left on earth that are unspoiled. Sri Lanka is one of them. Once known as Ceylon, Sri Lanka has Asia's best game preserves. 200 species of animals, 425 kinds of birds and hundreds of square miles of leopard, elephant and sambur.

The wild flowers of Sri Lanka include a dazzling display of orchids. And where else could you find 600,000 acres of tea gardens on misty mountains?

There are 75 ways you can tour Sri Lanka. Ranging from 3 to 21 days. Accommodations begin at $5. Deluxe sells for $45. Never has your dollar worked harder. From shopping to sightseeing.

In our ancient cities, you can enjoy frenetic festivals that reflect the unspoiled nature of a culture which dates back 3,000 years.

Whether your visit is pleasure, business or a convention, our unspoiled country will spoil you. Just one hour from India, three hours from Katmandu, Bangkok and Singapore. Write for a color flyer and tour digest that includes special airfare.

member to let out his pig. The pig grew big and fat, and the bigger it grew the more corn it ate. That pig never seemed to get enough corn. In October my son butchered that pig. Then all the families of his relatives came to see that dead pig, and to every family my son gave a big piece of meat. In four days all the pig was eaten. My son says it does not pay to raise pigs."

"But this reservation has fine grazing lands," I said. "Why don't you keep milch cows?"

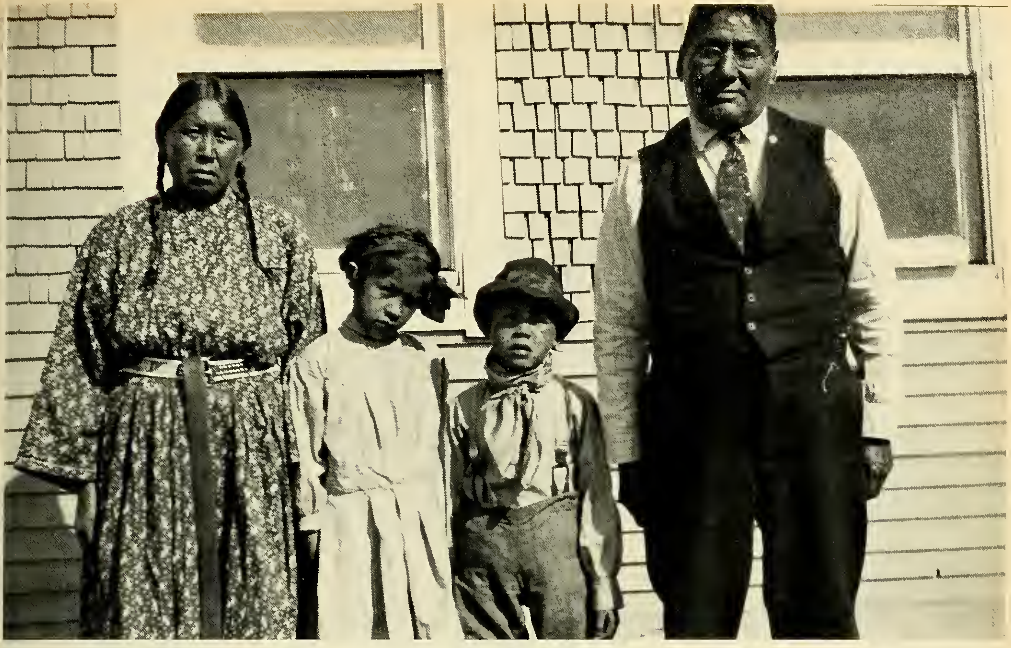
"We tried to keep milch cows," answered Wolf-eye, "for we liked the milk. But none of our older Indians can read or speak English. The Government has allotted us farms and tells the Indians they must live on their farms. But these farms are far apart. The 500 Indians of my small tribe are scattered for fifty miles along the Missouri River. They have no books to read, no magazines to amuse them. An Indian family becomes lonesome and goes to visit friends; maybe they cross the Missouri in a flat boat, and are gone two or three weeks. When they come home again they find their cows dry; or the cows are wild, and kick if the Indians try to milk them. Also the coyotes have stolen the Indian's chickens. One cannot keep a strong heart when things are like that."

"But your young men are educated in our schools. If they are ambitious, they can join white communities and live like white men."

"That is hard to ask of them. A young man's heart yearns for his own people. In olden times, a young man was ambitious. He was eager to be a warrior, not that he liked to fight, but if he struck an enemy, everyone praised him, girls smiled at him, and he could marry any one he wanted. White men are ambitious to make money, so that others will think well of them, and they can marry into good families. But we Indians cannot get rich on this reservation, where all our relatives visit us and eat our food. There is now nothing to make us ambitious."

"But if your young men are educated and know English, why cannot they compete with whites, and get rich as white men do?"

"That is not easily done. Our reservation schools are not good, and an Indian lad is not equipped as a white boy is equipped. Then, even if a young Indian has a strong heart, there is not much he can do on this reservation and his relatives often try to keep him back in the Indian ways."



*Wolf-eye and family, 1913*

# Hard-to-find classics at hard-to-find prices.

Let us send you the book of your choice from this list of 15 classics. It's yours for the token price of just $1, as your introduction to the Classics Club.

The Classics Club is unlike any other book club. It doesn't offer best sellers that come and go. Instead, it offers its members a chance to stay young through great books that never grow old; in collector's editions for just $7.39 a volume. (Little more than the cost of a quality paperback.) And there is no minimum number of books you must buy.

As a member, you can select the books you want to own from a list of more than 40 great works of literature, history, biography, and philosophy. Many of them are rarely found in bookstores today—and then, often only in paperback. These volumes are remarkable values. They're hardbound in matched wheat-colored buckram, worked and stamped in crimson, black, and 23 karat gold. And through direct-to-the-public distribution, we are able to offer our members these deluxe editions for only $7.39 each, plus shipping.

Interested? We'll send you your introductory selection for only $1 plus a few cents shipping. Don't send any money now. We'll bill you later. Just fill in and mail the coupon now while you're thinking about it.

1. Sir Francis Bacon *Selected Essays*
2. Honoré de Balzac *Old Goriot*

La Partera

The Story of a Midwife

by Fran Leeper Buss

Jesusita Aragon was fourteen when she earned the title "La Partera," midwife. This is her story, told in her own words, of her training as a midwife, her forced departure from home and the solitary struggle to support her children, and of her emergence as a community leader, often the only source of medical care in an isolated area of New Mexico.

$10.95/paper $6.95

The University of Michigan Press

Dept. AL P.O. Box 1104 Ann Arbor, MI 48106

"Cannot many of your young men find employment with white people?"

"Some of them do, but white men often refuse to employ Indians. Even if trained to some trade, an Indian raised on our reservation cannot know the thousand-and-one little things that will make him at home in white society and which are such a help to one's work."

"But white men usually treat Indians kindly, do they not?" I asked. "Americans admire the Indians. Many books are written about Indians and their customs."

Wolf-eye answered with feeling, but he spoke calmly.

"For twenty years I have tried hard to learn white men's ways. In all that time I have met but three white men who treated me like a brother, Mr. Hall, the missionary, an agency clerk, and a man who came to us from the American Museum of Natural History. We Indians are proud. It hurts our hearts when white men tell us we are greasy and dirty. We do not like to have them say, 'You are just like dogs!' We Indians know very well how we live, and that our old customs do not fit into the life our young people must learn to live. In old days, every young man went each morning for a bath in the Missouri; in winter he cut a hole in the ice, and after his bath, rubbed himself with white clay. We lived then in Like-a-fishhook Village, right on the river. Now our families are, many of them, two or three miles from the river, and we have no baths in our cabins.

"Our clothes are not neat and clean, like white men's clothes. In olden days, we dressed in skins, which we could clean with white clay. Now our clothes are of cloth, and we do not know how to care for them. Many of our women own washtubs, and know how to use soap; but it is hard for them to heat water in our cold winters. Our cabins are small; our women cannot take their tubs out of doors in the biting wind, when the ice is four feet thick on the Missouri; and if they wash the clothes in the cabin, the air gets full of steam while the water that splashes on the floor freezes. Then the door is opened to let out the steam and the room gets cold; so we build a hot fire in the stove, until we have to open the door again, to cool the cabin. Our children thus catch cold, and have lung sickness."

"But you have more to eat now than you had when you lived by hunting, have you not?" I asked.

"Yes, but we do not know how to prepare many of our new foods. In old days, when a buffalo was killed, our women knew how to cook every part. But our women cannot make things like rice, potatoes, wheat, and oats, into good-tasting foods. And this I think very bad for sick people. An Indian woman's baby gets sick. The reservation doctor is maybe thirty miles away. That Indian woman gets scared. She does not know what to do. She remembers that when she feels tired, she drinks coffee, and it makes her feel good. So she makes a big pot of coffee, and gives it to that baby. Maybe that is why so many babies die on this reservation."

"But you have many things, now, that you did not have then. Do you not live more comfortably?"

"In many ways, yes. We have iron axes, and iron hoes and guns. Iron axes make the work of our women easier. When I was a boy, we still lived in earthlodges, which our women built. My grandfather told me that it was hard to cut posts with stone axes, and split puncheons with horn wedges. Our iron hoes are better than our hoes of bone; and we can cultivate more corn now that we have plows.

"But I am not sure that gunpowder has been a blessing. For a time that made it easier to hunt game, but the buffalo herds were soon killed off. Then, in olden days, when we fought with arrows, not so many men were killed. After the Sioux got guns, they could come opposite our village, and shoot across the Missouri at our women as they went down to get water. The Sioux could not have done that with arrows."

"I am sure horses are useful to the Indians," I said, "and you have other live stock, also."

"Yes, we have cattle; some families raise pigs, and not a few have chickens. But we have other live things from white people that we do not like. We have rats and a new kind of mice. We did have lice in old times, but we never had flat bugs that now get into our beds."

"But I hear that the Indians are having better health now that they send more often for the reservation doctor when they are sick."

"That is true. I think he understands many white men's diseases better than our medicine men do. Then, too, he tells us that in the white man's road we are now trying to travel, there are many things that make us have dis-

Why choose a JAL Happi Holidays Tour for your vacation in the Orient? For the same reasons you'd choose JAL to fly you there. Attention to detail, courtesy, patience, hospitality and thoughtfulness. Our top tour operators do all the planning, so all you have to do is sit back and enjoy the trip.

The way we plan your Happi Holidays Tours is the way we fly our airline. For us, there is no other way. It's the way we are.

**Oriental Heritage 25 Days, $3826**
Tokyo, Kyoto, Nara, Seoul, Manila, Singapore, Bali, Jogjakarta, Kuala Lumpur, Bangkok, Chiang-Mai, Hong Kong. Fully escorted tours, deluxe hotels, à la carte dine-around program, comprehensive sightseeing, all tips taken care of, tours restricted to 24 travellers.

**Orient Escape 21 Days, $2172**
Tokyo, Kamakura, Hakone, Kyoto, Bangkok, Singapore, Bali and Hong Kong. Local host escort, full American breakfast, dine-around program, comprehensive sightseeing and, in Japan, travel on the Bullet Train.

**Pacific Affordables—Far East 20 Days, $2138**
Tokyo, Kamakura, Hakone, Atami, Kyoto, Bangkok, Singapore, Bali, Hong Kong. Deluxe hotels, full American breakfast, dine-around plan available, comprehensive sightseeing, knowledgeable local escorts and, in Japan, travel on the Bullet Train.

**Orient Courier 15 Days, $1832**
Tokyo, Hakone, Kyoto, Taipei, Manila, Hong Kong. Deluxe hotels, full American breakfasts daily, special entertainment and special dinners, comprehensive sightseeing, Bullet Train from Hakone to Kyoto in Japan. Excellent local escorts.

Departures throughout the year.

Prices based on double occupancy and G.I.T. Economy airfare from the West Coast, and are subject to change. Additional charge for June-October peak season.

The way we are is the way we fly.

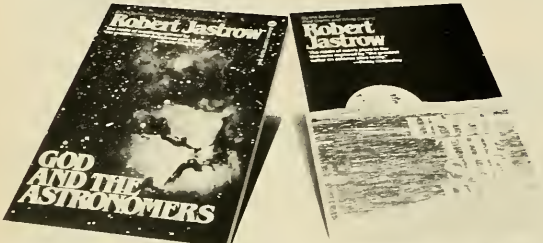
DOES SCIENCE FINALLY AGREE WITH THE STORY OF GENESIS?

TWO BESTSELLERS BY DR. ROBERT JASTROW
"THE GREATEST WRITER ON SCIENCE ALIVE TODAY"*



$4.95 $4.95

**Now in two companion paperback bestsellers,** the author of RED GIANTS AND WHITE DWARVES presents the clearest and most compelling answers yet to the ultimate questions men have asked since the beginning: How was the universe created? How did life arise? Astonishingly, he shows that the explanations offered by science are essentially the same as the Biblical account in Genesis!

GOD AND THE ASTRONOMERS
With extraordinary clarity, Jastrow explains the scientific evidence that the universe began in a giant explosion 20 billion years ago. If every effect in science has a cause, what caused the birth of the universe? Have scientists, with exquisite irony, brought themselves face to face with the possibility of God?

UNTIL THE SUN DIES Dr. Jastrow traces the chain of evolution from the first spark of life 3 billion years ago, through the age of the dinosaurs to Space Age homo sapiens. And he shows that the earth is among the youngest planets in the universe and that humanity is clearly an embryonic race, with roughly another 6 billion years until the sun dies.

**Illustrated throughout, including 8 pages in full color, plus a new foreword written especially for this edition!**

eases, that we did not know in our old life. He says we will get lung sickness if our cabins are not clean. My wife sweeps my cabin every day and I whitewash the outside and the inside twice a year. If my child takes sick, I send for the reservation doctor right away. But my father was a medicine man who said sickness comes from evil spirits. If the doctor does not come at once to my sick child, I sometimes sing one of my father's sacred medicine songs. I cannot always wait till the doctor comes. Once a man from a museum wanted to buy my father's medicines. I was afraid to sell them, because I knew the wonderful things those medicines had done. I worship the one, true God now, and I know it is wrong to worship my father's medicines, and I never do worship them. Still, I know the magic cures they have done, and I was afraid to sell them to the museum until one night I had a dream from my father's spirit that they would be put into a big house built of stone, in New York, where they would rest forever and white people could see them. I thought, too, that it was perhaps best to sell them away from the reservation. I am a Christian now and if those medicines are in New York the spirits that may be in them will not get angry at me because I do not worship them. It is very hard for me to be a Christian because I cannot read the Bible much in English, and so I cannot know all of God's commandments. Then, too, I see Christians do things which the missionary tells me are wrong when I do them. I do not understand it!"

"Your children will understand better, perhaps, because they are now being taught the Christian way in the mission schools."

"It is true; but they are learning many things that I cannot believe. The missionary teacher tells my son that the earth is round like a ball. That seems foolish to me. I have stood on the top of one of the Rocky Mountains, and the earth looked flat, just as it does here on the prairie. The teacher also says it is wicked to make war, and our Indian warriors did wrong in old days when they went out to fight other tribes. Why then do white men make war? In that big war in Europe, the Government took many young Indians from this reservation to be soldiers, to fight the Germans. Why don't white men leave off making war?"

And come to think about it, why *do* white men make war?

*NEW DISCOVERY*

# Carry-All Wardrobe

## A brand new concept in single piece, multi function luggage that reduces your travel time anywhere by 20 minutes or more.

There's good reason why carry-on luggage is the "in" way to travel. Fashion aside, it is a time saver and an aggravation stopper.

Anytime a Chicago to New York flight takes an hour and forty-five minutes and luggage retrieval takes an additional 20 to 30 minutes, there's need for a Carry-All Wardrobe.

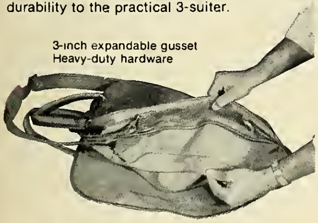
Each time you find yourself marking time by a carousel and experiencing a twinge of anxiety when your suitcases are delayed or lost, our Carry-All Wardrobe increases in value.

The Camelot Carry-All Wardrobe is entirely new — in design, styling and concept. Final production samples were four months in the making. Afterwards, our carry-on bag was "people-tested" by a variety of executives. Remarks like "convenient . . . comfortable . . . easy . . . peace of mind . . ." followed business trips to the Orient and throughout the states. We knew we had a winner. Especially when everyone asked, "How can you offer it so inexpensively?"

Luggage often follows a manufacturer, distributor, salesmen route with quite a few markups and commissions built in. Ours was built for us and comes directly from the factory. It could easily sell for $60 to $80. But, we've priced it to be an incomparable value.

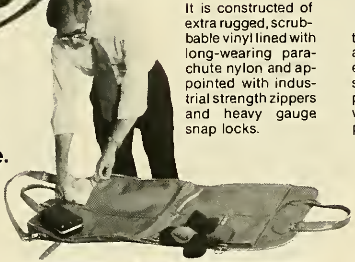
### BEAUTIFULLY STYLED

The Carry-All is finished in an exquisitely plush, deep brown, leather-grained polyurethane leather. Industrial strength zipper closures are handsome appointments that add long wear durability to the practical 3-suiter.



### A BAG FOR ALL REASONS

The Camelot Carry-All is a 3-suit, expandable garment bag with ample room for shoes, shirts, toiletries and anything else you might need for an overnight or week-long trip.



It is constructed of extra rugged, scrubbable vinyl lined with long-wearing parachute nylon and appointed with industrial strength zippers and heavy gauge snap locks.

### COMPARE ITS HOLDING POWER

Its overall size is approximately 38" tall by 22½" wide by 8½" deep. Aside from the 3-suit garment bag, there's a **suitcase compartment** with a built-in shoe bag and a wrap-around zipper that opens wide to accommodate a wealth of apparel.

There's a second zippered pocket that's 17" tall by 22" wide by 5½" deep with a 1" gusset and a zippered closure that can handle files, reports, extra shirts, etc.

If that's still not enough, the Carry-All has still another smaller zippered pocket that's perfect for jewelry, etc. And there's also a special tie rack that easily holds several ties neatly out of the way.

Best of all, the Carry-All is comfortably compact. It will hang like a carpack or zip up like a suitcase. When folded, it measures just 17" tall. You can carry it as a conventional case by its reinforced, cushioned handles or wear it on your shoulder. The adjustable shoulder strap is included. When folded, the Carry-All rests on five rubber feet.

Once aboard a plane, the Carry-All hangs by its built-in metal hanger. But, its most impressive feature becomes apparent when you deplane and bypass those baggage bottlenecks.

### ENJOY IT AT OUR EXPENSE

The Camelot Carry-All is truly unique and truly a value. It is a fine piece of luggage worth at least $60 to $80. It comes complete with pedestal feet, non-slip hangers and an adjustable shoulder strap. But if, after 10 days you are not pleased with its quality, versatility and convenient travel advantages, just return it. We will promptly issue your refund.

# THE NEW PLANET

## A DRAMATIC DISCOVERY

A Brief History of the Planets Known to Science, and the Most Recent Triumph of Scientific Investigation

BY CLYDE FISHER

*Then felt I like some watcher of the skies*
*When a new planet swims into his ken.*
—JOHN KEATS

THE finding of a new major planet had occurred but twice since the dawn of history—so one can understand the excitement occasioned during the early weeks of 1930 by the picking up of an ultra-Neptunian world. Predicted by the late Percival Lowell, and first "sighted" as a faint spot on a photographic plate, the discovery of the new planet was completely established by Director V. M. Slipher and the astronomers of his staff at the Lowell Observatory. A brief survey of the earth and neighboring worlds already known possibly will help us to appreciate this recent dramatic event, this triumph of scientific investigation.

To the ancients five planets were known, namely, Mercury, Venus, Mars, Jupiter, and Saturn. They, of course, did not know that the earth belonged to this group. In fact, for many centuries preceding the adoption of the Copernican theory of astronomy, it was thought that the earth was the center of the universe.

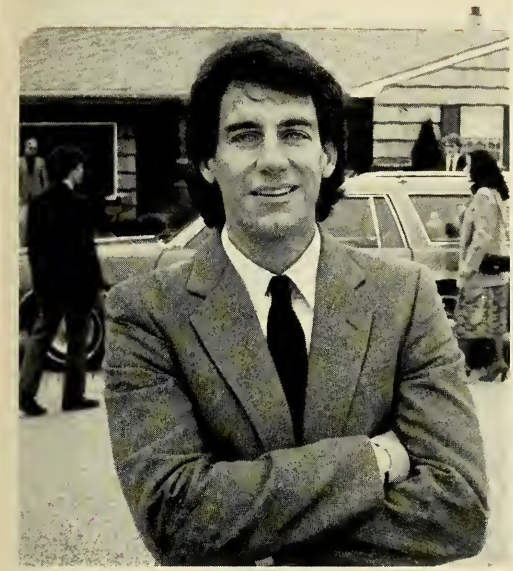
When we consider the matter, we realize that this geocentric notion was a natural conclusion to be drawn from observation. The sun was seen to rise in the east, to pass over the sky, and to set in the west, and the next morning it was again seen to rise in the east. It surely seemed that the sun went round the earth. The moon was seen to rise in the east, to pass over the sky and to set in the west, and the next day it was observed to rise again in the east. It also seemed that the moon went round the earth. (We now know the moon does go round the earth about once a month, but this motion does not account for its daily rising and setting.) The stars were also observed to rise in the east, to pass over the sky, and to set in the west, and the next evening the same ones were seen to rise in the east again. Thus it seemed that all the bodies in the sky revolved around the earth, and the earth seemed to be the center of the universe.

The great Ptolemy believed the earth to be the center of our family of planets, and his system was orthodox astronomy for fourteen hundred years. However, there came a time when this theory received a rude jolt. About the middle of the Sixteenth Century there was published a book by the great Polish astronomer, Copernicus, setting forth the theory that the sun is the center of our system of planets, and that the rising and setting of the various heavenly bodies is only an apparent motion due to the rotation of the earth on its axis.

Mercury is the innermost of the known planets, according to the Copernican system of astronomy. Although it is 36,000,000 miles from the sun, it is still so close to that huge incandescent body that it is generally overwhelmed by the light of the latter. It can be seen only when at or near its greatest eastern or western elongation, that is, when it makes the greatest angle with the sun. It is so close to the sun that it goes round that body in eighty-eight of our days. We are not quite sure whether Mercury has an atmosphere, but very probably not. It is believed that it keeps the same side toward the sun all the time, and that the temperature of that side is high enough to melt lead. Mercury, like all the rest of the planets, shines only by reflected sunlight, and since its orbit is inside that of the earth it goes through phases as our moon does, and for the same reason. If Mercury had any satellites, it is believed they would have been discovered at one of the recent transits of the planet across the sun.

Venus is the second planet in order from the sun, and it makes the circuit around that central body in 225 of our days. Venus comes closer to the earth than any other of the major planets. It comes nearly ten millions of miles closer than Mars. When at or near its closest position to the earth, Venus is the brightest object in the sky except the sun and moon. There are only two known planets that can go through the crescent phase—one is Mercury and the other is Venus. The first person to see Venus as a waxing and waning crescent was Galileo. If Venus had any satellites, it is believed they would have been discovered at the last transit of Venus across the sun. Only two planets can come between us and the sun, namely, Mercury and Venus. The last transit of Venus occurred in 1882, the next will be in the year 2004. Very little is known about the surface of Venus because of the dense, opaque atmosphere which surrounds the planet. This member of the solar system may have been given the feminine name because of its great beauty as a morning or evening star. When Venus is near the earth and the telescope reveals it as a thin crescent, resembling the new moon, the observer is no less charmed by the surprising beauty.

The earth is the third planet from the sun, although the ancients did not realize that it was one of the group of wanderers through the sky, five of which they knew besides. On our imaginary journey from the sun, the earth is the first planet that is known to have a satellite, and this satellite, which we call the moon, is the only body in the sky which goes round the earth. The moon



# One of these men drives himself to work, drives himself home and drives up his cost of living.

He doesn't see it that way. He's been driving himself to the office every day for several years now. He actually enjoys the ride.

Problem is, with today's energy crisis, the man on the right is wasting both fuel and money. Gas prices alone make the trip expensive. And his auto insurance premium is higher than it has to be.

The man on the left has decided to conserve and save. When the gasoline shortage began, he and some neighbors started carpooling to work. So together they consume less gas. That cuts expenses right there. What's more, because each of them drives fewer miles, they save money on their auto insurance as well.

As a major group of property and casualty insurance companies, we're doing our best to help you keep your insurance rates affordable. That's why most auto insurers are offering discounts to those individuals who reduce the total number of miles or times they drive to work.

For example, people who normally drive 30 miles to and from work every day can save up to 22% on car insurance premiums just by carpooling. All they have to do is drive to work two days a week instead of five.

People who switch to public transportation to get to work save even more on their premiums—up to 31% in some states. Their car becomes classified "for pleasure use only," a less expensive category.

**Here's what we're doing to control costs:**

■ Offering premium discounts to those who reduce the total number of miles they drive each week to work. Discounts will vary by company, by state and by the type of coverage you have.

■ Cracking down on insurance fraud practices through the Insurance Crime Prevention Institute and the National Automobile Theft Bureau.

■ Working through the Insurance Institute for Highway Safety to make cars and roads safer.

■ Investigating injury and repair claims more thoroughly.

**Here's what you can do:**

■ Cut down on your driving by carpooling or by using public transportation.

■ Use your auto seat belt and shoulder harness.

■ Talk to your insurance agent or company about ways to lower the cost of your auto insurance coverage.

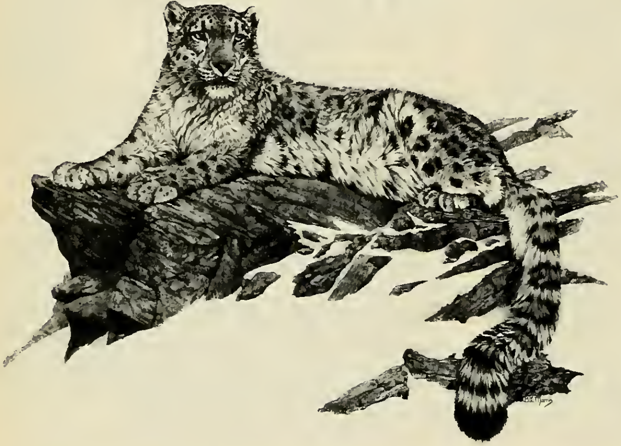
■ Lock your car. Don't invite trouble.

## Affordable insurance is our business...and yours.

This message is presented by the **American Insurance Association,** 85 John Street, New York, New York 10038.

YOU CAN HELP SAVE THE SNOW LEOPARD

برفانی چیتا



اِس خوبصُورت جانور کو قانونی تحفّظ حاصِل ہے
مگر آپ کی مدد کے بغیر یہ زندہ و پائندہ نہیں رہ سکتا
اسے زندہ رہنے دیں
یہ پاکِستان کا قیمتی سرمایہ ہے۔

The SNOW LEOPARD is almost extinct and it is protected by law in Pakistan. The export of a Snow Leopard skin is illegal and will jeopardize the survival of this beautiful animal.

Time is running out for the magnificent Snow Leopard. Although it is protected by law, native poachers, using snares, guns, and poisoned spears, are exterminating this high mountain cat for its luxurious pelt. Only a change of attitude among local peoples toward this unique animal can save the Snow Leopard from extinction.

In an effort to reduce poaching in Pakistan and instill pride in this "National Treasure", RARE produced and distributed 2,400 bilingual posters to schools, airports, government offices, shops, and other public areas. Latest reports from local officials charged with enforcement of laws protecting this beautiful cat have been most encouraging. The Pakistan government has requested 1,000 more posters. In addition, RARE would like to expand this campaign to include those areas in India and Afghanistan where remnant populations of the Snow Leopard are found.

For a contribution of $10 or more (tax-deductible), you will receive one of these handsome, *full-color* posters (actual size: 18″ × 24″)—widely acclaimed one of the handsomest wildlife posters ever—and help RARE continue this campaign. We hope you will be as generous as you can.

Please make your check payable to "RARE, Inc." and send to:

*Rare Animal Relief Effort, Inc.*

completes this circuit in about four weeks, as can easily be observed.

The mountains and craters on the moon were first seen by Galileo, through the first astronomical telescope ever made. These features of the moon's surface may be observed best at first quarter or on the two nights thereafter, or at the equivalent time about last quarter. At full moon there are no shadows to bring out the relief of the moon's surface. There are several ranges of mountains on the moon, the lunar Apennines being the most extensive. This is a slightly curved range four or five hundred miles long, and rivaling the Andes of South America in height.

The so-called seas, so named by the ancients, are now known to be plains, for there is no water on the moon. A large part of the surface of the moon is abundantly covered by craters of all sizes up to one hundred miles in diameter, named for astronomers, philosophers, and others. The Crater Copernicus is fifty-six miles in diameter while the Crater Tycho has a diameter of eighty miles. Two theories for the formation of these craters have been advanced, namely, the volcanic theory and the impact theory. According to the former they are thought to be due to volcanic action in a manner similar to the formation of volcanic craters on the earth. According to the latter they are supposed to have been caused by the falling of meteorites or planetesimals into the moon. There is one crater on the earth which seems to give weight to this theory, and that is, Meteor Crater in Arizona. Aeons ago there may have been many more on the earth, but if so, the agencies of erosion would probably have removed

**There's a Spanish legend that promises golden sun, blue Caribbean days, the nighttime whirl of roulette tables...in Cartagena and Santa Marta, Colombia. Including Avianca jetfare.**

**$416** Price from Miami based on double occupancy, Group 5 weekend departure. First class hotels for 7 nights, sightseeing tours, U.S. departure tax, transfers, and services of American Express Hosts/Hostesses. Both tours also available from New York and Los Angeles.

**Come dance the Bossa Nova and step into 22 days of lost civilizations, bikini'd beaches, Euro-Latin sophistication as can only be found in unforgettable South America. Including jetfare. $1,786.40**

It's deluxe and first class all the way: Colombia, Ecuador, Peru, Argentina, Brazil, Venezuela, including ancient Machu Picchu, spectacular Iguassu Falls, Buenos Aires and Rio. Sightseeing tours everywhere, 5 breakfasts, 2 lunches, based on double occupancy and Avianca jetfare from Miami (individual tour fare). Also available from N.Y. and L.A.

I'll talk to my travel agent, but send me a brochure anyway.
Avianca Vacation Center, 4299 N.W. 36th Street, Miami Springs, Florida 33166
Spanish Legend and Bossa Nova are American Express Tours. They're as fabulous as they sound. We have more information.

# ¡Speak Spanish like a diplomat!

What sort of people need to learn a foreign language as quickly and effectively as possible? *Foreign Service personnel*, that's who. Members of America's diplomatic corps are assigned to U.S. embassies abroad, where they must be able to converse fluently in every situation.

Now *you* can learn to speak Spanish just as these diplomatic personnel do—with the Foreign Service Institute's Programmatic Spanish Course.

The U.S. Department of State has spent tens of thousands of dollars developing this course. It's by far the most effective way to learn Spanish at your own convenience and at your own pace.

The Programmatic Spanish Course consists of a series of tape cassettes and an accompanying textbook. You simply follow the spoken and written instructions, listening and repeating. By the end of the course, you'll find yourself learning and speaking entirely in Spanish!

**This course turns your cassette player into a "teaching machine."** With its unique "programmatic" learning method, you set your own pace—testing yourself, correcting errors, reinforcing accurate responses.

**AUDIO-FORUM**®

The FSI's Programmatic Spanish Course comes in two volumes. You may order one or both courses:

☐ Volume I, Basic.
(11 cassettes, 16 hours), instructor's manual and 464-page text, $115

☐ Volume II, Advanced.
(8 cassettes, 11½ hours), instructor's manual and 614 page text, $98
(New York residents add sales tax.)

Your cassettes are shipped to you in handsome library binders.

**TO ORDER, JUST CLIP THIS AD and mail with your name and address, and a check or money order.** Or, charge to your credit card (American Express, VISA, Master Charge, Diners Club) by enclosing card number, expiration date, and your signature.

**The Foreign Service Institute's Spanish course is unconditionally guaranteed.** Try it for three weeks. If you're not convinced it's the fastest, easiest, most painless way to learn Spanish, return it and we'll refund every penny you paid! Order today!

Many other FSI language courses also available. Write us

Bushnell Give Us A Look

If you'd like to reduce the size and weight of your binoculars to an 11 ounce and 3 inch high instrument that will give you the resolution and light gathering you need, you'll want to see Bushnell's new Custom Compacts. At your Bushnell dealer or write Bushnell Optical Co., Dept. NH54, 2828 East Foothill Blvd., Pasadena, Ca 91107.

them. Since there is neither atmosphere nor water on the moon, these craters, regardless of their origin, have probably changed little or none. Their large size, whatever may have been their origin, is probably correlated with the lesser force of gravity on the moon than on the earth. A man weighing 150 pounds on the earth would weigh about twenty-five pounds on the moon. Therefore volcanic matter, or matter thrown by the impact of a body falling into the moon, would be thrown six times as far as on the earth. The moon with its "seas" and mountains and craters is a magnificent object through even a small telescope. One's first sight of the moon through the telescope can never be forgotten.

Mars is the fourth planet from the sun, and next outside the earth. It is the one that appeals most to the popular fancy, on account of the perennial question of whether there is life on this neighboring world. Although Mars does not come as close to the earth as Venus, we are able by means of the telescope to make out much more about its surface, due partly to the greater transparency of the atmosphere of the former. Mars presents a ruddy surface relieved by darker areas, polar caps, and the much-discussed "canals."

The polar caps can be seen with a small telescope, and they have been observed to change in size according to the season, just as the polar caps of the earth do.

The line-like markings on the surface of Mars, which were first designated "canals" by Schiaparelli, have occasioned much discussion. Whether they are waterways bordered by vegetation, thus making them wide enough to be seen through our larger telescopes, is still an unanswered question.

The axis of Mars is inclined almost the same as that of the earth; hence, the planet must have similar seasonal changes, since there is atmosphere and water on the planet, but on account of the longer time required for revolution around the sun (687 days), the seasons must be nearly twice as long as those on the earth. A Martian day is 24 hours and 37+ minutes in length.

Since the temperature of the surface of Mars has been measured and found not too low to preclude the possibility of life, and since there is air with oxygen, and since there is water as vapor in the clouds, which however are rare, and solid in the polar caps, and probably liquid—these conditions consid-

WSI
Air Alive
NATURAL · AIR FRESHENER

Attractive Air Alive unit measures only 4½" x 4" x 1¾" and cleans a 20' x 15' x 8' room in up to 15 minutes.

# AIR ALIVE

## *Uses "Nature's Air Cleaners" to electronically destroy odor, smoke, dust, and pollen. Now research shows it may do more!*

Little-understood particles, called negative ions, are said to be nature's best air cleaners. They attach themselves to dust, smoke, pollen or anything else floating in the air, and cause it to fall harmlessly to the ground. Now there is growing proof that negative ions may affect your moods, health and sense of well being.

### THE ION CONTROVERSY

For the past 20 years, scientists and scholars-world wide have been studying the effects of electronically charged particles in the air called negative ions.

Russian scientists have recently proven that the presence of ions in the air is essential to animal life. Research conducted at the University of California has shown that plant growth is stunted when the ion content in the air is decreased.

Some researchers claim there's evidence that negative ions can relieve allergic ailments and headaches, help control virus, retard the growth of bacteria, increase mental alertness and energy, reduce pain, tension, fatigue and depression and produce sound sleep.

Interestingly, while the number of those who believe that negative ions do, in fact, produce these benefits, has grown, the number of doubters has decreased over the years.

### THE ION IMBALANCE

The air is made up of molecules that contain either a majority of electrons, making them negative particles, or a majority of protons, making them positive particles.

Although nature produces a nearly equal number of positive and negative ions, there are a number of reasons why we are surrounded by an over abundance of protons: air pollution depletes the number of negative ions in the air, the static charge from synthetic fibers produces positive ions and natural earth radiation, that would normally produce negative ions, is retarded by concrete and asphalt covering the land.

In effect, we are breathing air that nature never intended us to breathe ... air that has been depleted of negative ions. What is needed is a way to correct this ion imbalance.

### NATURE'S AIR CLEANERS

There is almost no disagreement among scientists that negative ions are unmatched in their ability to cleanse the air of impurities.This is how they do it: negative ions attach themselves to dust, smoke and pollen, neutralize them and cause them to fall harmlessly from the air.

Engineers and doctors have recently recognized this benefit and have begun to take advantage of it. Many now use commercial units that emit negative ions and effectively destroy odors and pollutants in the air.

It has only been during the last year that technology has developed an affordable consumer model. These units were first introduced in Europe where there is a high level of interest in the benefits of negative ions.

Now we are introducing one of the first consumer units to be sold in this country!

### ONE OF THE FIRST UNITS UNDER $100

When we were offered the opportunity to introduce Air Alive to the American market, we jumped at the chance! Why? Because it's one of the first consumer models in this country to be sold for under $100. And because it's manufactured by Western Systems, Inc., a pioneer in the ion generation field.

### MOST COMPACT UNIT ON THE MARKET TODAY

Air Alive measures only 4½" x 4" x 1¾" and puts out 3 trillion negative ions per second per cubic centimeter.That's as many or more than larger, more expensive units now on the market. It is so powerful that it cleans a 15' x 20' x 8' room in up to 15 minutes. Air Alive brings you more cleansing power in its compact size.

### WARRANTED FOR TWO FULL YEARS

Air Alive is an all solid state unit ... it has no moving parts. The unit is so trouble free that it is warranted by Western Systems, Inc. for two full years, in the unlikely event that anything should go wrong.

THE
ION
EFFECT

### FREE BOOK JUST FOR TRYING AIR ALIVE

*Just for trying the Air Alive unit, we are offering a 160 page book entitled "The Ion Effect".*

**Absolutely Free!**

It is yours at no additional charge. It's yours to keep even if you should return the Air Alive unit during our 30 day trial period "The Ion Effect" traces one man's 10 year effort to discover the truth about the effects of ions. Judge for yourself the benefits of negative ions.

### OPTIONAL AUTO ADAPTER

Now Western Systems, Inc. brings something new to the American market that Europeans have used for years . . . an optional auto adapter that allows you to use your Air Alive home model in your car, truck, van or RV. Hardware included for mounting under your dashboard and adapter plugs into your cigarette lighter.

### 30 DAY NO-RISK TRIAL

We believe Air Alive to be the most compact negative ion generator on the market today. It will destroy the dust, smoke, pollen and odors in the air in your home, office or car.

And we want you to decide for yourself whether or not you can benefit from the effects scientists are claiming that negative ions can have on your health and sense of well being.

We offer you a 30 day, no risk trial period on every Air Alive unit you order. If during that time you decide the Air Alive unit does not meet your expectations, for any reason, you can return it for a prompt refund of the purchase price.

DISCOVERY TOUR TO THE NILE

American Museum of Natural History
Discovery Tours

Discover the world of ancient and modern Egypt on an American Museum 600 mile Nile Cruise. Explore with three lecturers the rich natural and archeological sites of an area which has fascinated visitors for centuries. A carefully planned itinerary (with a special two-day program in London visiting the British Museum and London Zoo with their keepers) provides a relaxing and thorough three-week Discovery Tour. All of the major Nile archeological sites as well as the important wildlife regions are discussed and visited with your balanced team of eminent lecturers. Share with Museum staff and friends an unforgettable cruise. October 19, 1980 or February 8, 1981. For further information and itineraries write to the **American Museum of Natural History, Discovery Tours**, Central Park West at 79 St., NY NY 10024, or call (212) 873-1440.

ered together with the motions of the planet—it seems to be the consensus of opinion among astronomers that there is life on Mars.

Jupiter is the next major planet outside of Mars. It is the largest of the planets, and requires nearly twelve years to go round the sun. It rotates on its axis in a little less than ten hours. It has four large satellites and at least five small ones. The four large moons were discovered in 1610 by Galileo. The observed variations in the times of the eclipses of Io (one of the Galilean satellites) with the varying distance of the earth from Jupiter led Roemer in 1675 to make the first determination of the velocity of light. Jupiter presents only an outer surface of cloud, and definite bands in these surface clouds can be seen easily through a small telescope. The surface of Jupiter is cold, the thermocouple indicating approximately 100 degrees below zero.

Saturn, the sixth planet, is considered by some to be the most beautiful telescopic object in the sky, due to the rings, which were formerly referred to as "the fiery rings" of Saturn. Now it is known that these rings are composed of myriads of small solid bodies or moons, and that they are cold. Besides the rings, Saturn has eight relatively large satellites and one or two small ones. Saturn is so far from the sun that it takes nearly thirty years to go round the sun.

Uranus, the seventh planet from the sun, was discovered in 1781 by Sir William Herschel. He saw it as a hazy disc, slowly moving among the stars, and at first thought it to be a comet, and announced it as such to the Royal Society. Very soon, however, its planetary character was established, and Herschel named it Georgium Sidus in honor of the King of England. The name, "The Georgian," was used in the *Nautical Almanac* up to 1850, but it was disliked outside of England. Lalande proposed the name, "Herschel," which is found in some of the old books. Bode proposed the name Uranus. The planet has a revolution period of 84 years. Uranus has four satellites, the orbits of which are inclined to the plane of the planet's orbit and to the ecliptic more than 90 degrees, so that the motion of the satellites is really retrograde.

Neptune, the eighth major planet in order from the sun, was discovered in 1846, after its elements had been computed independently by Adams and Leverrier, the story of its discovery

# Invite the King of Comedy into your home ...and look at all the friends he'll bring:

**Bing Crosby • Al Jolson • Eddie Cantor • Judy Garland • Sammy Davis Jr.**
**Kermit and Miss Piggy • The Supremes • Raquel Welch • Pearl Bailey**
**Ethel Merman • Fibber McGee & Molly and many, many more!**

**"If success is judged by the number of friends," said Bob Hope, "I've been very successful."**

Now you can invite Bob and over 40 of his friends into your home to help you relive 50 of America's greatest years: the Bob Hope years of comedy, humor, melody and—most of all—memories.

From Vaudeville to Viet Nam, Fibber McGee and Molly to Miss Piggy and the rest of the Muppets, our King of Comedy is one of the few entertainers who has conquered the stage of Vaudeville and Hollywood... radio and television... the silver screen and the silver jets, racking up *more than nine million miles* in the air!

Three long-playing records put you right there with George Burns, as he and Bob, Groucho Marx, Jack Benny and Danny Thomas pay tribute to the immortal Palace Theatre. You'll be on the scene in 1941 at the USO show at March Field... at another somewhere in the South Pacific... listening to your radio as the "Pepsodent Hour" goes on the air... and on the "Road" to everywhere with Bob and Bing.

Every minute of this incredible treasury is authentic history, reproduced from old broadcasts and records, then electronically enhanced for today's sophisticated stereo equipment. And it is packaged in a deluxe presentation case, framed in teak, with an easel for easy display!

In addition to priceless hours of entertainment and nostalgia, this treasury also includes a fabulous, oversized 52-page book, packed with more than 160 photographs, ranging from four-year-old Bob in a sailor suit to the Hope family today, plus a supporting cast ot politicians and soldiers, singers, dancers, humorists, and just plain people who helped make America what it is today.

Never before has there been so versatile an entertainer, one so decorated and admired as Bob Hope. And never before has his life and achievements been offered in such a memorable collector's treasury. It's a festival of amusement and memories that spans the generations... a collection you'll be proud to own and display and *enjoy*. So don't delay. *It is not available in any store, and we cannot guarantee this low price forever.* Please place your order today.

Invite Bob and his friends into your home for 30 days. Then invite *your* friends in to listen and enjoy. If you are not completely satisfied—if you don't agree that this collection is both memorable and outstanding entertainment—simply return it within 30 days and we'll refund your money. In full. There's no risk whatsoever—except that you might miss out on an outstanding opportunity!

BOB HOPE COLLECTION, P.O. Box 6326, Denver, Colorado 80206.

# BOB HOPE AND HIS FRIENDS

**Golden Anniversary 3-Record Album with Teakwood Framed Portrait Display Case and Bob Hope's 52-page Photo-History.**

**Standard sets with records plus 52-page book only $19.95 (in slipcase)**

## YOUR COLLECTOR'S PACKAGE INCLUDES ALL THIS FOR ONLY $29.95:

- 3 12-inch LP's made of super-thick 100% vinyl to assure long-lasting quality, electronically augmented for today's sophisticated equipment.
- A handsome, heavy-duty presentation case complete with its own easel, featuring a beautiful portrait of Bob Hope framed in actual teakwood, ready for display.
- An oversize 11"x11" 52-page book, with more than 160 photographs of Bob, his family and friends
- Also available in 8-track tapes or cassettes. Teak-framed Bob Hope portrait included.

**30-Day No-Risk Money-Back Guarantee**

**BOB HOPE COLLECTION, P.O. BOX 6326, DENVER, COLORADO 80206**

**YES,** please rush me BOB HOPE AND FRIENDS in my choice of sets indicated below. I understand I must be satisfied, or my money back.

probably being the most dramatic event in the history of astronomy up to that time. The planet was found almost exactly where these two astronomers had calculated that it should be, from irregularities in the orbit of Uranus. Neptune requires nearly 165 years to complete one revolution around the sun. It has gone only about half way around the sun since its discovery. Neptune has one satellite, the orbit of which is inclined to the ecliptic 145 degrees. Hence the revolution of this satellite is definitely retrograde.

On March 13, 1930, the scientific world and the general public were thrilled by the announcement of the discovery of a ninth major planet. On January 21st preceding, it had been "sighted" on a photographic plate as a faint spot, by Clyde Tombaugh, using a stereo-comparator. After this its motion was observed for more than seven weeks before public announcement was made of the discovery. Had it been a comet, it would have been observed to be moving rapidly toward or from the sun. The possibility of its being a comet was soon ruled out. By studying its motion, making allowance for the motion of the earth in its orbit, the revolution period of the new planet was approximately determined. Then its distance from the sun could be calculated from its period. This distance considered with its magnitude made possible the calculation of its size.

The new planet was found in the constellation, the Heavenly Twins, near the third magnitude star, Delta Geminorum. At Lowell Observatory it was estimated to be 15th magnitude. Since that time at Harvard Observatory it has been estimated to be 16th magnitude. It is probably about the size of the earth, at any rate much smaller than Neptune. Its distance from the sun is approximately 4,000,000,000 miles. Its period of revolution around the sun is estimated to be between 300 and 500 years.

Light, which travels 186,000 miles a second, or 11,000,000 miles a minute, takes more than six hours to come from the new planet to us. The sun's disc, if viewed from the new planet, would be about as Jupiter is to us on the earth.

Judging from the experience in the cases of Uranus and Neptune, it seems probable that the new planet will be given some mythological name in keeping with the custom.

---

*The planet was named Pluto.*

### A SUPERB COLLECTION OF

# Antique Forgeries!

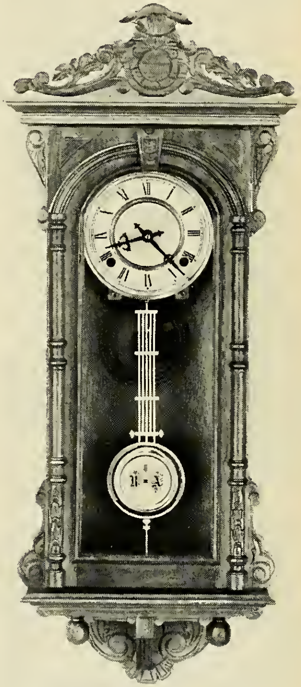
### FEATURING ALMOST IMPOSSIBLE-TO-FIND STYLES ...AT A FRACTION OF THE COST OF THE ORIGINALS!

If you enjoy lovely old clocks, and treasure the wonderful warmth and friendly atmosphere they create - then you must collect these marvelous antique re-creations for your very own. These are not ordinary, high-gloss, new-looking reproductions...but, rich, mellow-finished, true-to-life re-creations that look like a priceless old antique should. You get all the beauty and charm of a true antique, plus the solid 'carefree' performance of a new clock... all, at a fraction of the cost of the originals. So hurry, supply is limited - order your fabulous forgery today! Guaranteed for one year,

**#75 THE FLORAL BOUQUET**

**#4 THE SCHOOLHOUSE CLOCK**

**#2 THE LIPPINZANER HORSE CLOCK**



**#50 THE CATHEDRAL CLOCK**

## ABOUT THE CLOCKS!

All the cases are 100% kiln dried solid wood. Sanded, stained, rubbed, and carved by hand. Pendulums are solid brass. Faces, traditional white with brass rims, black roman numerals and hands. The time-tested 8-day, keywind, solid brass movement chimes the hours - and is reproduced from the original Ansonia U.S. Patent of 1882. It features the Graham dead-beat escapement, lantern pinions, traditional ¾" X 96" X .013" blued steel springs.

**#2 THE HORSE CLOCK.** Circa; 1880. 36"L X 14½"W X 6"D. Walnut with walnut finish. Large glass door. Glass panels on each side. **Only $110.**

**#4 THE SCHOOLHOUSE.** Circa; 1880. 22"L X 12"W X 4½"D. Oak with walnut finish. Round glass door with brass bezel. Gold lettering on lower glass door. **Only $79.95.**

**#50 THE CATHEDRAL.** Circa; 1883. 31½"L X 13"W X 6"D. Oak with dark oak finish. Large glass door. Glass panels on sides. **Only $115.**

**#75 THE FLORAL BOUQUET.** Circa; 1885. 18½"L X 12"W X 4½"D. Hand-carved walnut with walnut finish. Round glass door. **Only $110.**

### BE CAREFUL AND REMEMBER...

a 'good' antique clock costs 3 to 4 times more than a reproduction. And, like all antiques, almost all the good clocks are in museums or private collections. What's leftover, are in such poor condition or with so much restored - their working ability and antique value are in serious doubt.

*SEPTEMBER/OCTOBER 1925*

# THE EUROPEAN STARLING AS AN AMERICAN CITIZEN

BY FRANK M. CHAPMAN

THE American Museum may claim the doubtful honor of being the birthplace of the first European starlings to be born in this country. It was soon after their release in Central Park in 1890 that William Richardson, then of the department of taxidermy, found a starling's nest under the eaves at the northeast corner of the north wing.

Since that date, the Museum has extended its area from Columbus Avenue to the park, but in the same period the starling has extended its range, locally, from Montreal to Florida and Ohio. The one hundred birds freed in 1890 and 1891 now have millions of descendants. The starling has come to stay. Nature has accorded him his "papers" and he exercises all the privileges of citizenship.

It is a singular thing that both the starling and English sparrow were introduced into New York City by the same person. Impressed by the abundance of birds in England and by what he believed to be their comparative scarcity in this country, Eugene Schieffelin determined to make good the deficiency.

Inspired by the highest motive, he might, under proper direction, have become the father of bird conservation in America and have saved for us species we shall never see in life again. But like many another pioneer reformer, he blazed a false trail. Organizing and incorporating at Albany a society for the importation of foreign birds into New York State, he followed the introduction of the house sparrow with that of song thrushes, chaffinches, bullfinches, skylarks, nightingales, and finally the starling. Only the first and last of his attempts to transplant European birds to our shores were successful and in them he took no small amount of pride. Often, after the release of the starlings, he came to the bird department to ask whether any had been seen recently, and he was particularly pleased when he learned that a pair had nested in the building.

These observations, made immediately following the introduction of the starling, when its future in this country was still uncertain, recall the experiences of an earlier generation of ornithologists who, with equal interest, reported seeing English sparrows! I quote from the annals of the *New York Lyceum* for 1867, page 287, where George N. Lawrence wrote:

> This familiar European species has been successfully introduced in New York, and colonies have been established at several distant points, where they could have been seen during the past winter. After the extreme cold of last January (1866) when the thermometer marked ten degrees below zero, I noticed them in their usual quarters, apparently unharmed. In Jersey City, also, they are quite numerous. I first observed them in the spring of 1865. A friend, conversant with our local native birds, informed me that he had seen a species in the shrubbery around the church on the corner of 5th avenue and 29th street, with which he was not familiar; on going to ascertain what they were, to my surprise I found them to be house sparrows; they were domiciled in the ivy which grew on the walls of the church, and were quite gentle and fearless, some alighting in the street and dusting themselve quite near to where I stood. I afterwards learned from our associate, Mr. Eugene Schieffelin, that he had been looking after them with much interest; in fact he is entitled to the credit, in a great measure, for this important acquisition to our city. In 1860, and for three years thereafter, he yearly set free five or six pairs, mostly in the neighborhood of Madison Square; seven pairs were let out in the Central Park by the Commissioners, in 1864.

After becoming thoroughly established in the upper part of New York City, the starling began the campaign for the acquisition of territory which is still in progress. Following shore lines it spread north, east, and south, and within ten years appeared at Ossining, New Haven, and Bayonne. Another ten years saw it near Providence and Philadelphia and in 1920 it was known from Maine to Virginia.

Having colonized the coastal region, like other emigrants from over seas, it began to penetrate the interior. It reached Ithaca, New York, in 1916, and the same year was found at West Lafayette, Ohio, the first known appearance of the species west of the Alleghenies.

The Plains, the Rockies, and the Sierras will probably prove obstacles in the starling's course, but no doubt he will surmount them and sooner or later establish himself throughout the greater part of the country.

During the thirty odd years of the starlings' residence in America, none of our native land birds has appreciably increased in numbers. How, then, has the starling, starting from a few pairs, become more abundant than many of them? In attempting to answer this question we discover some of the factors governing the comparative abundance of species. In the first place, it is evident that the starling has filled a place (technically, an "ecological niche") not occupied by a native species. Without in any way disparaging the American Museum as a home for birds, indeed we always welcome them, what American bird, left to its own resources in Central Park, would have reared a family under our eaves? The European house sparrow (which we insist on miscalling the "Eng-

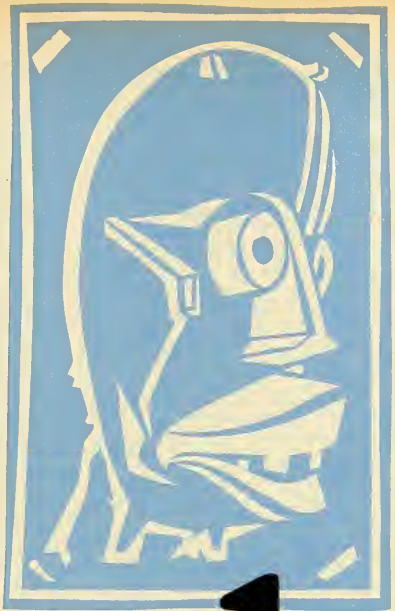
# Masks & martinis.

Bargain for a beautiful Dan
ask in the morning and enjoy a
licious martini in the evening.
ıe excitement, beauty and so-
ıistication of West Africa is wait-
g for you.

The African mask is not a
sguise. Nor is the wearer a man
etending to be a god. Rather,
ask and man become a god who
visible in its real form.

Music and dance were the
st African arts to attract the at-
ntion of travelers and histo-
ans. A shield from ancient
reece depicts an African
umpet player. African sculpture
as not appreciated until the end
the 19th century.

Among the Dan people who
/e in the Ivory Coast, the impor-
nce of a mask is in proportion to
s size. The biggest, most impres-
ve ones, the "Masks of Peace,"
e sufficiently powerful to end
ostilities between villages.



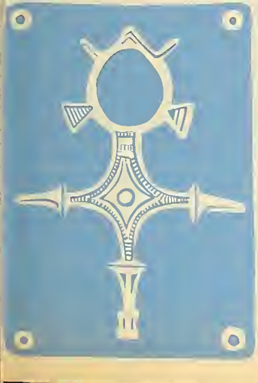
Much of the great African art comes from West Africa, and the best way to get to and around West Africa is to fly Air Afrique. We have the most complete schedule of interconnecting flights between West African cities, New York, Europe and the rest of Africa.

Part of the fun of West Africa is bargaining. So here are the rules of successful bargaining: 1. Start at half the price you're willing to pay. 2. Never hurry. 3. Always keep your sense of humor.

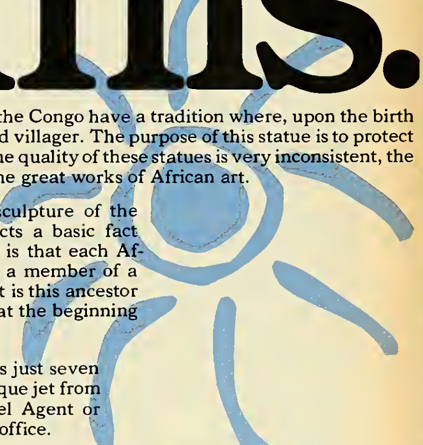
While African food is both varied and delicious, you'll be pleased to know that should you get a craving for Italian food, or French food, or Oriental food, you can usually find instant gratification in any major city.

By the way, if you like hotels with air conditioning and swimming pools, you will find a hotel to your liking in virtually every West African capital city.

The Cross of Agadez,
ɔne of the most famous silver
ewelry designs in all of Af-
rica, is worn by the Tuareg
people of the south Sahara
desert in Niger.



The Bateke people of the Republic of the Congo have a tradition where, upon the birth of a boy child, a statue is carved by a talented villager. The purpose of this statue is to protect the boy until he reaches puberty. Although the quality of these statues is very inconsistent, the best of them are worthy of a place among the great works of African art.



Ancestors appear frequently in the sculpture of the West African people. This emphasis reflects a basic fact about the nature of African existence, that is that each African is what he is and has what he has as a member of a family, i.e., the descendant of an ancestor. It is this ancestor sculpture that so amazed European cubists at the beginning of this century.

The great wealth of West African art is just seven hours away on a luxurious, non-stop Air Afrique jet from JFK. For more information call your Travel Agent or your nearest Air Afrique/Air France ticket office.

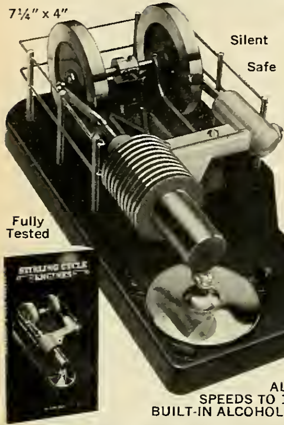
Traditional African cultures use basketry for a wide variety of purposes. Everything from houses to milk bottles are woven in beautiful designs from plant materials.

**AIR AFRIQUE**

Africa begins with Air Afrique.
And it's just seven hours to the New Sun…
West Africa.

The Amazing Stirling Cycle **Hot Air Engine**

**Heat is the only fuel required!**



A marvelous opportunity to acquire an early model Stirling Cycle Engine and acquaint yourself with little known facts about a product of the past that may well hold promise for the future.

The average person has never heard of the Stirling engine, so the sight of one quietly running with heat as its only fuel will at first amaze them and then excite their imagination. This is the first in a family of six different desk-top model hot air engines to be issued during the next three years.

**Experimenters • Hobbyists' Power Source**
**Students • Collectors • Model Engineers**

An easily read, lavishly illustrated, 128-page book accompanies each engine or may be purchased separately. This publication, the first of its kind, takes the reader on a 160-year tour through the world of Stirling Cycle Engines. Illustrations include the Stirling, Roper, Heinrici and the amazing new Stirling-powered Ford Torino!

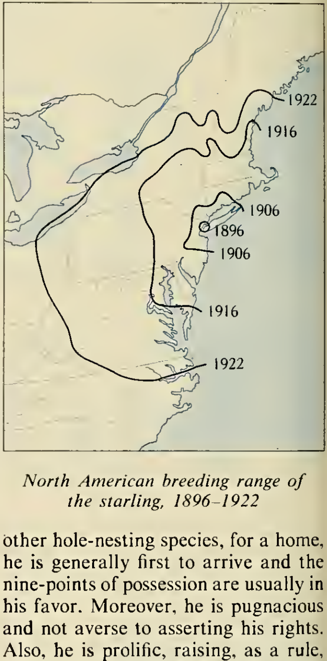
lish" sparrow) could and does, and like the starling it has succeeded. It is this ability to adapt themselves to circumstances which, primarily, has enabled these aliens to survive and flourish in America. Again, like the sparrow, the starling is hardy and non-migratory. This means that he can withstand wide climatic variations and, in default of an inherited habit which would lead him over routes followed by our birds, that he runs no risk of flying out to sea, or to some other place whence he might never return. It is true he wanders about after the nesting season, but his movements are largely governed by a search for food and probably do not carry him far from his nesting place.

When, therefore, he does have to compete with flickers, or bluebirds, or other hole-nesting species, for a home, he is generally first to arrive and the nine-points of possession are usually in his favor. Moreover, he is pugnacious and not averse to asserting his rights. Also, he is prolific, raising, as a rule, two broods, of which, because of the protective character of the nest-site and defensive ability of the parents, a comparatively large percentage doubtless reach maturity. Need of only limited territory when nesting is also presumably responsible for the starling's rapid increase. In some birds sexual jealousy is so highly developed during the season of reproduction that they will not permit another pair of their own species to nest near them. But, I have recently heard of five pairs

Joe LeMonnier



*North American breeding range of the starling, 1896–1922* of starlings nesting simultaneously in the hollow limbs of a single willow tree. Add to these various traits, omnivorousness in feeding habits, and we have some of the reasons why the starling has multiplied and spread.

Having with thoughtless hospitality accorded the starling, house sparrow, San José scale, gypsy moth, and other pests, including certain members of the genus *Homo,* free and unchallenged entry to our ports, we now ask (if to our sorrow, we have not already learned), "Are they desirable?" So far as the starling is concerned the question is not to be answered in a word. It can, however, be answered for we have to thank American economic ornithologists for the most exhaustive study of the starling's food habits which have as yet been made.

The starling is here considered under three counts: (1) its food habits, (2) its relation to other species, (3) its direct relation to man. The study of the starling's food has been conducted with great thoroughness and the results reached doubtless adequately express the bird's economic status at this period of its American history. They are summarized as follows:

As an effective destroyer of terrestrial insects, including such pests as cutworms, grasshoppers, and weevils, the starling has few equals among the bird population of the northeastern United States.

The most serious objection to the starling on economic grounds arises from its destruction of cherries. When its work is combined with that of the robin, which is fully as destructive and much less easily frightened, the chances for a successful crop of cherries, especially of early varieties, are poor.

The starling's work on apples is confined largely to isolated trees and to small, old orchards. Late varieties suffer more than those which mature at a time when there is still a great abundance of wild black cherries available. In the aggregate the apple damage is not great and is practically absent in young, well kept, productive orchards. Injury to peaches and pears is negligible, and the damage to grapes is at present confined to small arbors–the large vineyards suffering very little.

An idea of the economic significance of the starling's food habits is gained by comparison with the food habits of certain well-known native birds, with some of which it frequently associates. A thorough consideration of the evidence at hand indicates that, based on food habits, the adult starling is the economic superior of the robin, catbird, flicker, red-winged blackbird, or grackle. It is primarily a feeder on insects and wild fruit—less than 6 per cent

Splendid Isolation

*The Curious History of South American Mammals*

George Gaylord Simpson

In this book America's leading paleontologist traces the origins and histories of a group of animals that has intrigued scientists for centuries. Illustrated with striking sketches and restorations of these odd creatures, both living and extinct, the book captures the fascination of their story and clarifies the incomparable role it plays in an understanding of the process of evolution. 43 illus. $17.50

Yale University Press
New Haven and London

of its yearly food being secured from cultivated crops. What damage it does inflict is due not so much to the character of its food habits as to the fact that the flocking habit has allowed some minor trait to be emphasized to a point where local damage results. The decidedly beneficial character of the food habits of one, two, or sometimes three broods of nestlings, numbering 4 to 6 to the nest, adds materially to the favorable economic status of the species.

The starling's competition with American birds is largely restricted to those that nest in holes and similar sites. This includes chiefly the bluebird and flicker. The former is no match for the relentlessly persistent alien and even the flicker's larger size does not always prevail against the starling's aggressive tenacity.

Conflict over the food supply is negligible in summer, but serious in the autumn and winter. For example, a dogwood bearing a crop of berries sufficient to supply a group of gentle-mannered hermit thrushes with food for a fortnight will be stripped by a flock of starlings in a day. As a result, the thrushes continue their migration southward to winter beyond the present range of the starling. But it is apparently only a question of time when the starling will be abundant in winter at least throughout the Gulf States where it will claim no small part of the food supply of our native species.

There are times when the starling makes such strong demands upon our hospitality that even its friends resent its presence. This is during the late summer and early autumn when the vast flocks of birds select a city park or village lawn as a roosting place. Grackles, robins, and martins are often associated with them and the whole may number many thousands. To the ornithologist such gatherings possess great interest, but the tired business man, who has come home to sleep, not to study avian communism, sees in them only a source of noise and filth, and spares no effort to induce the birds to move elsewhere. Frequently, however, he finds it difficult to convince them that they are not welcome. The usages of civilization forbid the murder of even the most undesirable guest, and in default of firearms, Roman candles have been effectively employed. Discharged into trees laden with sleeping birds, they create consternation without fatalities and finally make it plain to the feathered throng that, while we may encourage their coöperation in our gardens we

can dispense with them after nightfall. But the direct contact of the starling with man extends far beyond its roosting habits. These other relations, however, belong among those "imponderables" which science can neither weigh nor measure. They have to do with the personality of the starling, with its standing as a citizen and as a neighbor.

When a stranger enters an established community, he is bound, more or less, to disturb existing conditions, and the extent and nature of the local reaction to this disturbance determines his community status.

Viewed from this standpoint the starling is heavily handicapped. In the first place he is a foreigner. Now whatever we ourselves may be, whether our forbears came over in the Mayflower or on the Mauretania, there can be no doubt that our birds are Americans. As such they are not only the products but expressions of their environment. When, in early March, a moving nebulous blur resolves itself into a flock of redwings, they are less birds than the Spirit of Spring. But if the hurrying smudge becomes a passing troupe of starlings, we regard it with disappointment or indifference. It has no seasonal significance.

So the notes of the wood pewee voice the dreaminess of a mid-summer day —uttered by the starling, they are a mimetic travesty. But, after all, it is only the chosen few who cherish these intimate associations with nature that resent the starling's violations of them. To by far the greater number of those who notice him at all, a starling he will be and nothing more.

# TAUNGS AND ITS SIGNIFICANCE

## BY RAYMOND A. DART

MAN is an omnivorous, bimanous, and bipedal, almost erect, terrestrial mammal. The highest living anthropoid apes are frugivorous, quadrumanous (or quadripedal), semi-arboreal, semi-erect mammals. It is believed that man arose from a semi-arboreal ancestor, to which the highest living apes are the nearest mammalian relatives, and that this semi-arboreal ancestor sprang, in turn, from an ancestor who was entirely arboreal in habit. Indeed, there are those who believe, that not merely man and all his near relatives, the Primates, but the whole mammalian stock came from ancestors who at one time lived entirely in the trees. We are not concerned here with this more remote origin of the Primates other than to note that they are tree-livers and that their ancestors were tree-livers from the earliest mammalian times.

In order to achieve his so-called erect posture and terrestrial mode of life, the monkey that was to be man had to pass through a severe apprenticeship, of which there were two initiatory phases, before he entered the third phase or true freemasonry of manhood. These two phases were firstly, the semi-arboreal (or semi-terrestrial) which is typified by the living anthropoid ape; and secondly, the entirely terrestrial man-ape phase which has been hitherto typified by one representative only —the man-ape of Taungs [*Australopithecus africanus*], found in Bechuanaland, South Africa.

It has long been recognized by naturalists that two such phases in man's evolution were probable; of the first phase we have in the four living anthropoids and many extinct ones a great deal of information concerning not only its essential characteristics but also its site of operation, i.e., in the tropical or subtropical forest zone. The second phase has been appreciated only as a theoretical necessity, and the scene of its occurrence has been purely a subject of conjecture.

The Taungs remains show that this second phase was a living reality; they demonstrate that man did not arise "Minerva-like in full panoply" as a sudden sport from some semi-arboreal ape, but that the anthropoid achieved human status by laborious passage through the terrestrial man-ape phase; finally they indicate, if they do not actually prove, the quarter of the earth upon which this penultimate act in the drama of humanity was staged.

It is in these matters that the Taungs remains have their significance. They have rendered real what hitherto has been theoretical.

The Taungs limestone deposit is a cliff at whose feet, to the east lies the treeless (save for shrubs) valley of the Harts River and whose plateau crest, equally devoid of forest, stretches west into the Kalahari desert. The temperature at Taungs fluctuates from 120° F. in summer to severe frosts and biting cold winds in winter. The average annual rainfall is about five inches.

It is an area which impresses one, by its heat in summer, and its cold in winter, and by its lack of rain, of woods, of grass, of running water, and all things delectable, as the most inauspicious spot for man's forerunners. It is a region once thickly populated by Bush people and is now a native reserve occupied by a bastard Bush-Bantu race of Bechuanas. But areas such as this, habitable by mankind through his adaptability, his intelligent use of weapons, and his quickness of movement, are not habitable by the lumbering anthropoids of the tropics.

Hence, the appearance of *Australopithecus*, roughly on the latitude of Johannesburg, was most unusual and unexpected and can be explained only by the fact that *Australopithecus* has partaken of those characterstics which separate man from the anthropoids and make it possible for him to exist in such untoward environments. This belief that *Australopithecus* profoundly differed from modern apes becomes more reasonable when we consider the geographical situation of Taungs. Lying in the Orange River

*Raymond A. Dart*

# We pay these scientists to make our production lines obsolete.

As soon as there's a better way to do something, the old way becomes obsolete.

And these scientists do nothing *but* design new and better ways for Western Electric to manufacture products for the Bell System. In the last two years, they and their colleagues at Western Electric's Engineering Research Center have helped cut costs by over $156 million.

They are a vital part of Western Electric's commitment to helping the Bell System keep the cost of communications service down, while keeping the quality up.

## The Factory's Laboratory

The people at our Engineering Research Center work full time on manufacturing research. Over 50% of them are PhD's.

At home in the factory as well as the lab, they turn theoretical experiments into real savings. For example, while exploring ways to improve production of telephone circuit boards, they invented a totally new material with which to make the boards and a whole new way to mass-produce them.

Another breakthrough is already saving more than $2 million a year. It's a new soldering technique that makes 20,000 connections in less than 60 seconds.

The list of money-saving developments goes on. A new computer program that makes technical drawings in one-fourth the time of manual methods. An automatic system for sorting telephone parts by color. A process that measures the production of optical fiber 1000 times per second, keeping its diameter accurate within 30-millionths of an inch. And there's a new system that takes only 30 seconds to help align tiny integrated circuits that are 200 times thinner than the thinnest human hair.

These are just a few examples of what the Engineering Research Center does throughout *all* of Western Electric's manufacturing operations—developing new ideas in technology to improve telephone products and produce them at lower cost.

## Anticipating the Future

Much of the work of the Engineering Research Center is designed to keep Western Electric ahead of technology, by anticipating what new processes will be needed for tomorrow's products.

It's a total and ongoing commitment. A commitment to provide you with the highest quality telephone service at the lowest possible cost.

*Keeping your communications system the best in the world.*

**Western Electric**

watershed, it is separated from the Zambesi watershed by a vast open tract of country which, to the west (from Western Rhodesia to the Atlantic Ocean) is the Kalahari desert, and to the north and east (throughout Rhodesia and the Northern Transvaal) is occasionally wooded but is mostly treeless prairie or veldt country. There is no woodland approach to Taungs from the north, east, or west. This open and in large part barren country, interposed between the tropical forest and Taungs is, and has been from Cretaceous times, an effective barrier against the migration of the semi-arboreal anthropoids of Africa—the chimpanzee and gorilla.

The efficiency of this barrier against the migration of the living anthropoids cannot be stressed too greatly when we call to mind the fact that during Tertiary times that barrier of desert and plains has been effectively reinforced by the fearsome carnivorous enemies of Primates, whose possession it was. It is obvious, *prima facie,* that the Australopithecoid group which forced this barrier into the remote Southland had evolved an intelligence (to find and subsist upon new types of food and to avoid the dangers and enemies of the open plain) as well as a bodily structure (for sudden and swift bipedal movement, to elude capture) far in advance of that of the slothful, semi-arboreal, quadrupedal anthropoids. They had thus attained a degree of physical and psychical advancement that sundered them irrevocably from their tropical cousins. It is equally clear that those who had successfully traversed the barrier and established their capacity to live in the latitudes of the Vaal had no serious barrier interposed between them and the southern extremity of the continent.

We may therefore reasonably indulge the greatest hopes of the discovery of youths and adults of the same and allied species in any part of Southern Africa, especially the Eastern coastal areas where the climatic and botanical conditions are so much more amenable for Primate existence.

The formidable nature of the land and animal barrier together with the vicissitudes of life, to which this Australopithecoid group was continually exposed in this country, is the more important to bear in mind since the factors which evoked the thinking and planning powers of the anthropoid, and, with these powers, caused the transformation from anthropoid to

man, are to be sought, not in any cataclysmal upheavals of nature, or fortuitous saltations of the germ plasm, but rather in steadily and continuously operating environmental conditions which constantly and increasingly demanded the operation of choice and cunning.

Such an environment is certainly not to be found in any land belt containing the easy refuge of trees where the return to semi-arboreal existence was possible as, for example, throughout Southern Asia and the Eastern Indies.

Just as for the expansion of the brain so, for the evolution of a more erect posture, in which reliance would be placed upon the feet and not at all upon the hands, it was essential that a large territory should be available in order to make it impossible to return to the forest. In this way the anthropoid group should be committed over a countless number of years to the use of their upper limbs for fight and their lower limbs for flight. An environment of this type was present, because of the barrier already mentioned, from the Cretaceous times onward in Southern Africa; and Southern Africa is the only country which has elicited, hitherto, an anthropoid individual betraying features such as one might expect to result from the operation of these unremitting and compelling environmental conditions.

With reference to the epoch at which the fossil was embedded in the limestone, there is bound to be much doubt until we know considerably more about the geology of the deposits themselves, and the general question of ageing deposits in Southern Africa. From a consideration, firstly, of the position of this specimen in the cliff; secondly, of the intensity of the infiltration of the lime to form the hard stone in which it was embedded; and, thirdly, of the fact that there is ample evidence in the cliff itself that sand was being incorporated in the cliff during the depositing of the lime, I am of the opinion that the limestone was deposited irregularly leading to the cavernous structure, and that the interstices were filling up with sand from a very ancient period, in large measure contemporaneously with the lime deposition.

In his notes on the baboons found at Taungs which he has kindly placed at my disposal, Doctor Haughton remarks, "It is certain that the sandy patches in the limestone and the bones

LEARN TO THINK LIKE A PHOTOGRAPHER.

It is a rebirth of the mind. Simple surroundings take on a new meaning, a new dimension. It is the world of photography, and you can be an integral part of it through the innovative new McGraw-Hill Photography Workshop.

In the convenience of your own home, at your own pace, you'll learn to think like a photographer. You'll be given projects to utilize your newfound skills. A panel of professional photographers will critique your work and stimulate your photographic senses. You'll even have the opportunity to win photographic competitions.

embedded in them are of the same age as the main body of the limestone."

Since there was a certain growth forward as well as in height during the lime deposition, both the horizontal depth (250 ft.) as well as the vertical depth (50 ft.) at which the remains lay have a degree of significance. In other words I look upon the fossil as Tertiary and embedded while the lime formation was still in progress.

Since that time a ravine about one hundred feet in depth and nearly three-quarters of a mile long has been worn through the hard calcareous tufa when it was the original course of the tiny Thabaseek "river," a sluit or creeklike tributary of the Dry Harts River.

Later the "river" was diverted to its present course northward of the tufa through the softer shales, and has worn its bed to a point some two hundred feet below the top of the cliff. How long it has taken for these processes to become completed it is difficult to say, but in view of the fact that years may elapse without any running water ever passing over the "waterfall" at the head of the gorge through the plateau's edge and along the stream bed, and the further fact that water rarely, if ever, is running during a whole week in any year that rain falls—when of course it may be a raging though small torrent for a couple of days—it is impossible that the work of erosion could have been rapid. It is hardly necessary to say that in the period during which the area has been known, i.e., the last half-century, no appreciable alteration of the conformation of the stream or its channel has been recorded. Assuming for the sake of argument a uniform rate of backward erosion of ⅛ inch per annum, it will be seen that some 125,000 years were necessary for the formation of the dry ravine which is from 50 to 250 feet broad—the cutting of the modern river bed taking perhaps a somewhat briefer but additional period. At all events it is reasonable in the present state of our lack of knowledge to estimate the age of the river bed in terms of hundreds of thousands of years—possibly, as one has suggested, contemporaneously with the uplift of South Africa in the Pliocene. In any case the deposition of the lime deposits took place prior to that period, i.e., prior to the formation of the dry ravine and the present river bed, and so at a very remote period, probably pre-Pliocene. There is no evidence to indicate

that the Taungs man-ape did not inhabit the district in those days of lime deposition.

---

When Dart discovered the Taung skull and wrote his famous 1926 article for *Natural History*, anthropologists were divided in their responses to the extraordinary claims from southern Africa. There was uncertainty about many aspects of the strange creature: its geographical dispersal, antiquity, diversity, way of life, and place on the evolutionary tree. Almost everyone doubted Dart's outlandish claim that a creature with a brain size scarcely different from that of the apes, and one-third as big as that of modern man, could have been a near relative of the human species. They also doubted that humanity had its origins in Africa.

In the ensuing years, Africa's sedimentary deposits and dolomitic cave formations have yielded a broad array of evidence that has answered many of the questions provoked by the Taung skull in 1926. Fossils of *Australopithecus* have emerged from the Transvaal, Tanzania (where Olduvai is located), Kenya, and Ethiopia. Convincing specimens of *Australopithecus* have not yet been found in Asia or Europe. So far, *Australopithecus* represents an early African phase in human evolution.

The application of new technology has given insights into the age of *Australopithecus*. The earliest well-attested members are dated to just under four million years ago. A few older specimens, which might have represented the same group, might possibly take the earliest known members to over five million years. Thus, the genus existed during the Pliocene epoch of the Tertiary period and persisted into the Pleistocene, the first epoch of the Quaternary period. The most recently dated forms lived about a million years ago. Thereafter, *Australopithecus* disappeared from the record. The dating of the Taung skull itself is still problematical, however; estimates of its age hover between 1,500,000 and 750,000 years.

Careful anatomical studies have shown that most of the features of *Australopithecus* relate them to human beings. They walked upright, as Dart originally inferred; their hands, pelvises, legs, and feet were humanlike in structure; their brains, although small, resembled miniature human brains rather than ape brains; their teeth, although large, showed a human rather than an ape pattern. They are classed as hominids, or members of the human family.

Several kinds or species of *Australopithecus* occurred. The earlier ones, which lived mainly in the Pliocene, were gracile; they belonged to the species *A. africanus*. The later ones, which lived in the end-Pliocene and on into the Pleistocene, were a heavily built Transvaal version, *A. robustus*, and an extremely large-toothed, sturdy East African form, *A. boisei*.

Most scientists agree that the earlier, gracile *A. africanus* was most likely to have been on or close to the lineage leading to the genus *Homo; A. robustus* and *A. boisei*, on the other hand, were a specialized branch that died out about a million years ago.

Although scientists still argue about the names to be assigned to various fossils, there is nearly universal agreement that some populations of *Australopithecus* were most likely to have been ancestral to modern man. With hindsight, we see that Dart was right when he claimed that a small brain alone was not sufficient to disqualify the creature from the exalted company of hominids.

*Phillip V. Tobias*

*Paleoanthropologist Phillip V. Tobias holds the same position in the Department of Anatomy at the University of the Witwatersrand in Johannesburg, South Africa, that Raymond Dart occupied fifty-five years ago when the Taung skull was discovered. Since 1977 Tobias has also been an honorary professor of paleoanthropology, and this year became dean of the medical faculty, a position Dart also held.*

You'd expect Italy's airline to come up with something special to Italy.

We did.

Alitalia's 1980 tour brochure offers no fewer than 34 terrific tours to Italy. If you've ever shopped for an Italian tour, you know just how special that really is.

But we don't just offer incredible variety. As Italy's airline, Alitalia gives you the best that Italy has to offer. Expertly selected hotels and restaurants. Superbly planned itineraries. All in a country where the dollar still buys a lot.

Send today for your free copy of our big color brochure. It's called "Italy loves you." You'll love it.

Alitalia Tour Department NHN-P
666 Fifth Avenue, NY, NY 10019

Yes, I'd love a free copy of your "Italy loves you" tour brochure.

*SEPTEMBER/OCTOBER 1923*

# THE JAPANESE EARTHQUAKE EXPLAINED

BY CHESTER A. REEDS

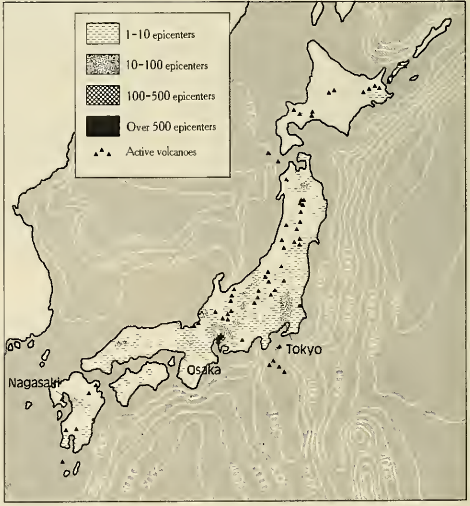
At noon on Saturday, September 1, 1923, Tokio time, the Empire of the Rising Sun was stricken by a power beyond human control. A violent earthquake shook Tokio, Yokohama, Yokosuka, Odawara, Hakone, Chiba, and other points about the Bay of Tokio. Shortly thereafter fires arose in Tokio and Yokohama and almost entirely destroyed those cities. Seismic sea waves were also reported in some dispatches and contradicted in others. At any rate, the devastated region was completely isolated from the rest of the world for days. There were more than 3,000,000 people in the stricken zone at the time of the catastrophe and the loss of life and property was so great that even a week or more after its occurrence, reports were still far from being complete.

This great earthquake was registered on seismograph instruments on the opposite side of the earth and at intermediate stations. The arrival of the first set of earth waves in the eastern part of the United States was registered at 10:12 P.M., Friday evening, August 31, the main waves shortly before 11 o'clock, and the last waves at 3 A.M., September 1. It may be stated here that due to the recognition of the international date line along the 180th meridian, the corresponding time in New York and Washington was Friday, and due to the difference in longitude of ten hours the time here was 10 P.M., August 31, 1923. Some dispatches state that in Tokio the initial heavy shock lasted not more than six minutes. Whatever may have been the brief duration, the waves which arose from this shock were spread out for five hours on the seismographs in the eastern part of the United States. According to dispatches from the Imperial Meteorological Station more than a thousand "after-shocks," which were not recorded on distant seismographs, accompanied this quake.

The earthquake map of Japan prepared by Dr. Charles Davison in 1921 exhibits in a striking manner the earthquake and non-earthquake regions as well as the location of the eighty-eight volcanoes on or near the principal islands of Japan. This map indicates that the central portions of Japan, where active volcanoes are numerous, are singularly free from earthquakes. A perusal of Prof. John Milne's catalogue of Japanese earthquakes, in which 8331 are listed between the years 1885 and 1892, shows that to every quake that was volcanic there were five that were non-volcanic.

The Japanese Islands form an arc or festoon with the convex side facing the Pacific Ocean. Furthermore, the submarine features are of special interest. From the contour lines for each thousand meters in depth it may be observed that the Japanese Sea is shallow, with its greatest depth a little over 3000 meters. The Pacific Ocean, on the other hand, is very deep. The extraordinary basin called the Tuscarora Deep reaches a depth of 8000 meters at distances of from 110 to 240 miles from the coasts. The gradient is unusually steep, being 1 in 27 off the coast of Nemuro, a maritime village on the island of Yezo, 1 in 30 off the northeast coast of Hondo, or the main island, and 1 in 16 (to a depth of 3000 meters) off the southeast coast of Kazusa and Awa, near Tokio.

Prof. F. Omori, the Japanese earthquake specialist, has listed 221 destructive earthquakes in Japan occurring from the fifth century to the present. Of the total number, 114 originated inland, 47 under the Pacific Ocean, 17 under the sea of Japan, 2 under the inland seas, while the epicenters of 41 earthquakes are unknown. Of these earthquakes 10 were very violent: 3 of them occurred in central Japan, and 7 originated off the southeast coast, each of the latter being accompanied by seismic sea waves. During the same period there were 23 great sea waves on the Pacific coast and only 5 on the Japan Sea.



*Davison's seismic map of Japan, based on Milne's list of 8331 earthquakes for the eight years 1885–92, shows that the number of earthquakes recorded in the Tokio district during this period was less than ten; also that the 88 volcanoes are distributed throughout the mid-western portion of the islands, except the Fuji chain to the southwest of Tokio.*

Burpee's
SPRING
BULB
CATALOG
1980

# FREE–Burpee's 1980 Spring Bulb Catalog

### 36 full-color pages with over 150 bulb varieties for spectacular spring flowers

---

Send for your free copy of Burpee's 1980 Spring Bulb Catalog — order your bulbs for fall planting now and save 10% to 20% during Burpee's Early Order Sale.

Burpee's 1980 Spring Bulb Catalog is beautifully illustrated in full color, with 36 pages of over 200 photographs of 154 different bulb varieties.

There are 32 different daffodils, 68 varieties of tulips, along with many varieties of crocuses, hyacinths, jonquils and other bulbs. Some you will recognize as old garden friends, others are sure to become new favorites when they bloom next spring.

Burpee's 1980 Spring Bulb Catalog contains helpful bulb growing and planting information you will want to keep and consult frequently. It's filled with gardening hints and tips — bulb blooming times, how to plant for continuous flowering, and much more.

### Burpee sells only the finest quality bulbs

Don't confuse quantity with quality. Burpee bulbs are all fully developed, full-size, and of the finest quality, for spectacular spring flowers. They are freshly harvested in Holland, and each individual bulb order is packaged with extreme care. Burpee bulbs are then shipped to you undamaged, healthy, ready to plant—and *guaranteed to bloom the very first season*.

### The Burpee Guarantee

For more than a century Burpee has made this promise to gardeners — *we guarantee your satisfaction with any product you buy from us*. Of course, that promise includes our bulbs as well. Burpee guarantees every bulb we sell to the full amount of the purchase price. You may have your money back or a replacement within one year if you are not completely satisfied with the results.

So before ordering bulbs this year, we believe it will be well worth your while to look at what Burpee has to offer. And remember, if we receive your bulb order by June 30, 1980, you can *save 10% to 20%* depending on the variety and quantity of bulbs ordered.

To receive your FREE copy of Burpee's 1980 Spring Bulb Catalog, simply complete the coupon below and mail it to the Burpee address nearest you. We'll rush your copy to you, with all its savings. Mail the coupon today—Burpee's Early Order Sale ends June 30, 1980.

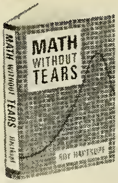
Similar results followed from Omori's examination of recent strong Japanese earthquakes. From 1885, when the systematic observation of earthquakes was begun, to 1905 there originated in or around Japan 257 earthquakes, some of which were destructive while the rest, although not involving great loss, were nevertheless strong or moderate shocks each having disturbed land areas of more than 25,000 square miles. The most active region at present stretches off the east coast of Yezo and Hondo, the number of earthquakes which occurred in it being rather more than half the total number in Japan. It is no great surprise therefore to find that the violent earthquake of September 1, 1923, took place in the Tokio district near the steep Pacific side.

An earthquake has been explained as the result of any sudden displacement within the earth's crust. It may have a tectonic or a volcanic origin. Tectonic earthquakes are due as a rule to the displacements which effect the growth of faults or fractures in the earth's surface. Volcanic earthquakes may be considered as those which are caused by volcanic eruptions or displacements along fractures of the volcanic mass, whether the volcano be active, dormant, or extinct. The volcanic earthquakes are of two kinds: first, those which are purely volcanic in their origin, and second, those which are somewhat tectonic in character.

From seismograms taken on certain active volcanoes of Japan, Omori divides the volcanic earthquakes into two groups: (1) those due to earthquakes which were not accompanied by any outburst of the volcano, and (2) those due to earthquakes which were invariably coincident with the explosions. The first group consisted only of simple quake vibrations; the second group began with slow tremors on which, after a few seconds, quick vibrations were superimposed. The earthquakes without explosions were distinctly the stronger, for of the 14,085 shocks of this character recorded from 1911–16, 21% were sensible, while of the 8847 quakes with explosions only 0.3% were sensible.

Tectonic earthquakes, the greatest of all, occur in regions somewhat distant from volcanoes or far removed from present or past volcanic action. They are due either to displacement along faults or to the warping of surface beds of rock in the earth's crust. As might be expected, faulting (the

MATH WITHOUT TEARS



Using non-technical language and a light touch Roy Hartkopf gives you a basic understanding of many everyday applications of mathematics. He takes the reader from simple counting to trigonometry and calculus, emphasizing the practical aspects of math. Humorously written. *Learn math in the comfort of your own home at minimum cost.*

*We repeat the enormously popular and unusually interesting outdoors programs to the Himalayas and the Andes, where our small groups are expertly led by capable mountaineers:*

The Ladakh Trek
JULY 1980

These expeditions include a trek through the lovely valleys and mountains of Kashmir into the remote country of Ladakh, which was until recently closed to visitors. Before and after the trek, first class hotel and houseboat accommodations are provided in Delhi and Srinagar.

Inca Trek in Peru
JULY, AUGUST AND SEPTEMBER 1980

These expeditions provide the stirring experience of walking along the ancient Inca trail from Cuzco high above the lovely Urubamba Valley, at a leisurely pace over three passes and through fabulous Andean scenery to Machu Picchu, the most dramatically spectacular archaeological site in the world. Before and after the trek, first class hotel accommodations are provided in Lima and Cuzco.

Himalayan Trek in Nepal
NOVEMBER 1980

These expeditions are unique not only due to the expert leadership but because they combine a trek on foot in the Annapurna region with a trek on elephant back through the Terai jungle, and a canoe trip on the Rapti River. Between the treks, first class hotel accommodations are provided; and the expedition ends with five days in Northern India, visiting Delhi, Agra and Jaipur.

*Please send for detailed brochures of these treks—we also specialize in cruises in the Galapagos Islands and the Hebrides, safaris to Rajasthan and East Africa and adventure tours to other unusual destinations.*

slipping of adjacent blocks of the earth's crust on one another along a fault-plane or fracture) predominates over warping in producing earthquakes. The connection between the crustal deformations and the earthquakes is shown by the coincidence between their times of occurrence and the areas affected by them. It is important, however, to notice that the deformations are not consequences of the earthquakes but rather the primary causes of the earthquakes. The number of earthquakes accompanied by crustal deformation is considerable. In many cases, however, the observations recorded add little to our knowledge beyond the fact that some movement usually of elevation has taken place. The principal reasons for connecting earthquakes with fault slips are the following: (1) with every step in the growth of the fault it is evident that an earthquake must occur; (2) in some great earthquakes the fault displacements are manifest; (3) in all but the weakest earthquakes the areas of greatest disturbance are elongated in form, their longer axes being parallel to the fault lines of the district; (4) the number of earthquakes in any region far exceeds the number of the faults; (5) in a series of associated earthquakes the center of the disturbance migrates to and fro in the direction of the fault; and (6) owing to the variations in the volume and displacement of the rock mass, fault slips are capable of producing the weakest tremor as well as the most violent shock.

The displacements along a fault may be almost entirely horizontal or almost entirely vertical, but in most cases they are both horizontal and vertical. Horizontal displacements are usually manifested by the relative shifting of objects previously in contact or in line; vertical displacements by the formation of fault scarps.

The great earthquakes which remove over-strained conditions in the earth's crusts occur after short lapses of time at different places in the seismic belt or related earthquake zones. They seldom, if ever, recur at one or the same spot, for the earth's stresses, having been temporarily adjusted at that place, accumulate in the adjacent seismic regions. Thus the Japanese earthquake of December 23, 1854, took place off the coast of Tokaido, while the equally extensive shock on the next day originated from the same earthquake zone 200 miles to the west, off the coast of Nankaido. Sympa-

**SOLID PROTECTION**

"This case is unbelievable, it's actually water tight when submerged completely under water. My work involves products, travel and adventure in the outdoors and underwaler, and these cases are the most rugged and reasonably priced of any I've seen." **BURTON McNEELY, ASMP,** Land O'Lakes, FL.

(In South Carolina, 1-559-5571.)

thetic stresses accumulating in widely separated parts of the Pacific seismic zone have been noted as follows:

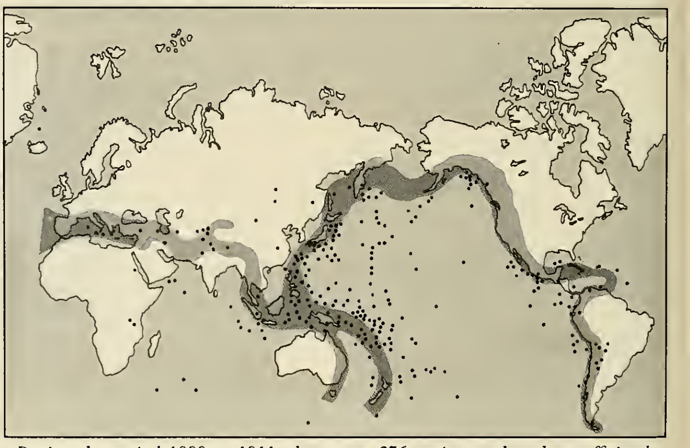
(1) Off the northwest coast of Alaska in 1899.
(2) Mexico and Central America, 1900 and 1902.
(3) Panama, Colombia, and Ecuador, February 1, 1906.
(4) San Francisco, April 18, 1906.
(5) Aleutian Archipelago, August 16, 1906.
(6) Valparaiso, August 16, 1906. (Note that Nos. 5 and 6 occurred on the same date, No. 5 occurring half an hour earlier than No. 6.)
(7) Chile, November 11, 1922.
(8) Six hundred miles northwest of San Francisco on the line of the San Andreas fault, January 31, 1923.
(9) South Pacific Ocean, February 3, 1923.

In this connection it is interesting to note that after the great Japanese earthquake of September 1, 1923, a sympathetic quake occurred in Calcutta, India, on September 10, and another one in Paotingfu, China, September 14, 1923.

A larger view of the problem is necessary in order to understand some of the underlying causes of the recent Japanese earthquake and of other earthquakes. In the distribution of earthquakes are to be found the loci of the most pronounced earth movements today, that is, the zones of present maximum change in the strained figure of the lithosphere, or solid part of the earth. In the case of the continental areas we have long known the position of the earthquake districts. The earth's crust trembles predominantly along two narrow zones which lie along two great circles of the earth known as the Mediterranean, or Alpine-Caucasian-Himalayan circle, and the circum-Pacific, or Andean-Japanese-Malayan circle. As to parts of the ocean floor which have been affected by these movements, it is only during the present generation that methods have been perfected for locating the sites of earthquakes beneath the seas. Modern seismographs, or earthquake-registering instruments, now record the sudden movements of the earth's surface quite independent of whether they occur at the bottom of the sea, upon distant islands, or upon the continents. The centers of large earthquakes, determined by the late Prof. John Milne for some fifty odd stations of the British Association for the years 1899 to 1911, appear as dots on the map on this page. It will be noted that the continental earthquake districts extend outward for a distance on the floor of the neighboring ocean and that the disturbances are more numerous for the undersea areas and belts of festooned archipelagoes east and southeast of Asia.

It may be noted further that the two main seismic belts are closely related to the geosynclines, or areas of sedimentation, dominant folding, and uplift during Cenozoic time, that is, during the last era into which geologists divide geologic time. This area may represent a period starting 3,000,000 years or more ago and continuing down to the present. The areas of dominant folding and uplift during Cenozoic time have been superimposed as shaded zones on the accompanying map. These two major circles of earthquake disturbance include within their limits the arcuate mountain folds known as the Pyrenees, Alps, Carpathians, Caucasians, and Himalayas of Eurasia and the Cascadian and Andean mountain systems of North and South America. These great mountain masses began their existence in the early part of the Cenozoic era and from their grandeur we might judge that they are almost completed, but from the rather frequent earthquakes that occur in and about them we must conclude that the earth forces which built them are still active although in their relative maturity. The mountains themselves are young and although not all of them are in the same stage of development, they are in their prime. The festooned island groups, however, such as the Japanese archipelagoes and similar arcuate forms off the southeast coast of Asia, as well as the Aleutian and West Indian arcs, represent younger mountain chains of the late Cenozoic age which are not yet fully exposed but are rising from the floor of the ocean.

Japan, the land of "cherry blossoms," is an island empire rising out of the sea. To most Americans Japan presents a detached group of mountainous islands beset with numerous volcanoes and frequented by earthquakes. The oceanic waters which surround these islands hide the stupendous mountain topography and the structure which powerful earth forces have already built up and which they are still erecting off the coast of Asia. Volcanoes and earthquakes are associated with the forces that build mountains, for they perform much the same function that safety valves do on a steam locomotive. For centuries Japan has had destructive earthquakes. Omori, who has studied many of them, concludes that the maximum epochs of destructive activity recur on an average every 13 or 14 years. From the nature of the case we may thus conclude that earthquakes will occur in Japan at rather frequent intervals for centuries to come. This prophecy, however, should not dishearten the Japanese nation, for, besides its own progressive development, it can take courage from the fact that the Babylonian, Egyp-



*During the period 1899 to 1911, there were 276 major earthquakes sufficiently severe to be recorded at all seismological stations scattered over the world. The epicenters are shown on the map as heavy dots. The close association of recent quakes to the belts of sedimentation, dominant folding, and mountain uplift (shaded zones) during recent geologic time (Cenozoic era) is very marked.*

tian, Grecian, and Roman civilizations developed about the Mediterranean, despite the fact that this region lies in one of the world's active seismic belts.

The Japanese nation is aware of its acute situation, for in accordance with an Imperial Ordinance dated June 25, 1892, the famous Earthquake Investigation Committee of Japan was organized. Its objects were to be: "In the first place to investigate whether there are any means of predicting earthquakes; and in the second place to investigate what can be done to reduce the disastrous effects of earthquake shocks to a minimum, by the choice of proper structures, materials, positions, etc." The Committee has included some of the most brilliant men of Japan and has now worked enthusiastically and tirelessly for thirty years; but no method of forecasting quakes has been discovered and the second endeavor is the only one which had been crowned with some success.

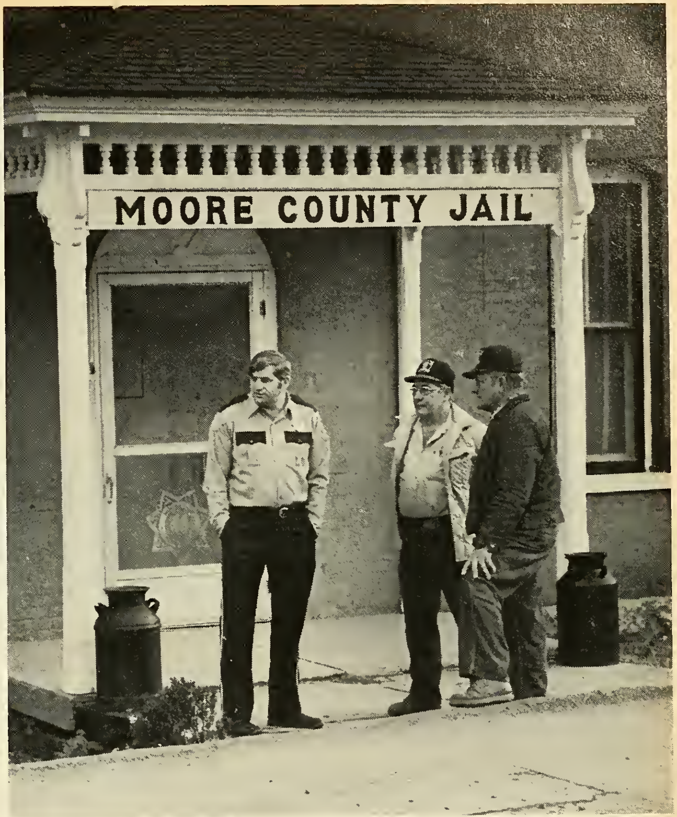
---

A moderate earthquake that struck near Coyote Lake, California, about sixty miles southeast of San Francisco, in August 1979, has cast serious doubt on hopes that reliable prediction of such an event will be possible in the near future. The quake, of 5.7 magnitude, occurred on the Calaveras fault, a major branch of the San Andreas fault, without any warning even though it fell within a dense network of monitoring equipment designed to detect just such an earthquake.

None of the usual short-term precursors of moderate quakes—clusters of small quakes, tilting of the earth's surface, or changes in the geophysical properties of the crust—were observed. This has caused great concern because evidence suggests that it is this type of moderate shock that triggers great, catastrophic earthquakes.

The feeling among some scientists is that the Coyote Lake quake may be an example of a class of nonpredictable earthquakes. The problem seems to be that, under certain conditions, small areas of high stress along a fault could make quake precursors hard to find. The level of stress necessary to produce a given precursor may be reached, but the precursor warning might appear over only the small area of the stress and not over the length of the fault. Or the stress may not be high enough to produce any precursors before the breaking point of the fault is reached.

In 1977, the funding of this country's earthquake prediction program was tripled. At that time, the estimate was that it would take ten years before instrument networks "captured" enough earthquakes of the right type to determine the practicality of earthquake prediction. After Coyote Lake, those in the business feel that it could take much longer.



If you'd like a booklet that tells you more about Lynchburg and what happens here, drop us a line.

THE MOORE COUNTY JAIL is only one of the sights you'll see in Lynchburg, Tennessee.

There's a lunchroom called the White Rabbit that used to be a turn-of-the-century saloon. There's a store where they sell walking-sticks, whittling kits and Tennessee hams. And naturally there's Jack Daniel Distillery where smooth-sippin' Tennessee Whiskey is made. If you're coming this way, we hope you'll spend time in all our nice places. Excepting, of course, the Moore County Jail.

Organized by the celebrated explorer Roy Chapman Andrews and sponsored by the American Museum of Natural History, the Central Asiatic Expeditions consisted of five journeys into Mongolia and China, undertaken between 1922 and 1930. This extraordinary venture resulted in the first systematic study of what was then one of the earth's least-known regions—the Gobi Desert. Audacious in concept, brilliantly planned and executed, the Central Asiatic Expeditions constituted the largest, best-equipped, and most costly program of land-based exploration ever launched from the United States up to that time. The budget totaled nearly $700,000—an unprecedented sum for such a project—and at the height of the most ambitious season, in 1925, the expedition included fourteen scientists and technicians, twenty-six native assistants, five touring cars, two trucks, and a caravan of one hundred twenty-five camels.

Using automobiles and supported by camel caravans that dropped fuel and supplies at rendezvous points, Andrews covered vast sections of the Gobi with a speed and efficiency never previously attained in desert terrain. Even by today's standards, the geographical range and scientific achievements of these expeditions were impressive. Among the discoveries were rich fossil deposits that contained an enormous variety of extinct animals and plants, including the now-famous dinosaur eggs laid by a creature known as *Protoceratops*, which lived approximately 100,000,000 years ago. Excavations at numerous archeological sites yielded a wealth of artifacts relating to Paleolithic, Neolithic, and historical cultures. Extensive studies were made of Mongolia's geology, an immense area of the Gobi was accurately mapped for the first time, and thousands of zoological and botanical specimens were collected.

These accomplishments often involved serious risks. In addition to natural hazards posed by the Gobi's harsh environment, Andrews and his companions had to contend with Mongol bandits, Chinese civil wars, and severe political harassment. Eventually, they were even thrust into the forefront of Sino-American relations when the project became the target of antiforeign sentiment in China. Indeed, at the conclusion of the 1928 season the expedition's collections—eighty-seven crates of fossils from Inner Mongolia—were temporarily confiscated by a militant group called the Committee for the Preservation of Ancient Objects; and only after prolonged negotiations between the American Museum, the Department of State, and the Chinese government was Andrews permitted to return to the field in 1930, when the events described in the following article occurred.

Unfortunately, 1930 proved to be the final season for the Central Asiatic Expeditions; despite a concerted effort by Andrews to continue his explorations, subsequent political developments in eastern Asia made further work impossible. "We had barely scratched the surface of the Gobi's secrets," he later wrote; and in terms of paleontology at least, this statement was remarkably prophetic. Intensive research conducted since World War II by Russian, Mongol, and Polish scientists has established the Gobi as one of the world's most prolific fossil-hunting grounds—a fact Andrews had suspected as early as 1918 when he first began formulating plans for his historic venture. *Charles Gallenkamp*

*Research associate in Maya art at the Museum of New Mexico in Santa Fe, Charles Gallenkamp writes and lectures on the archeology, ethnology, and pre-Columbian art of the southwest United States, Mexico, and Central America. In 1976 he received a grant for research on the explorer Roy Chapman Andrews, and with the cooperation of the American Museum, he is currently writing* Desert Quest: Roy Chapman Andrews and the Central Asiatic Expeditions.

*APRIL 1931*

# THE FATE OF THE RASH PLATYBELODON

## A Prehistoric Death Trap Yields Its Spoils—Persistent Exploration by the Central Asiatic Expeditions in Eastern Mongolia at Last Reveals the Most Favorable Conditions Under Which Remains of Ancient Man Might Be Found

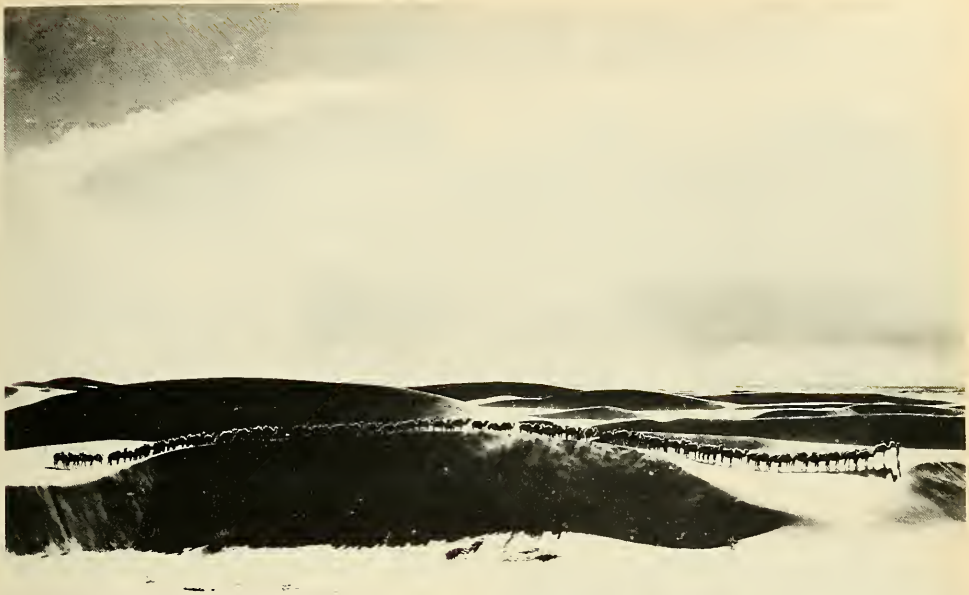
BY ROY CHAPMAN ANDREWS

I USED to believe that conducting explorations in the field was child's play in comparison to the difficulties of financing an expedition. But searching for the elusive dollar in the cañon of Wall Street is infinitely less nerve-racking than trying to steer a safe course for an expedition's ship between the rocks of Oriental diplomacy. Disturbed internal conditions and fluctuating politics present an almost unsurmountable wall to the foreign explorer. Weeks and often many months are required before permission can be obtained to go into the field.

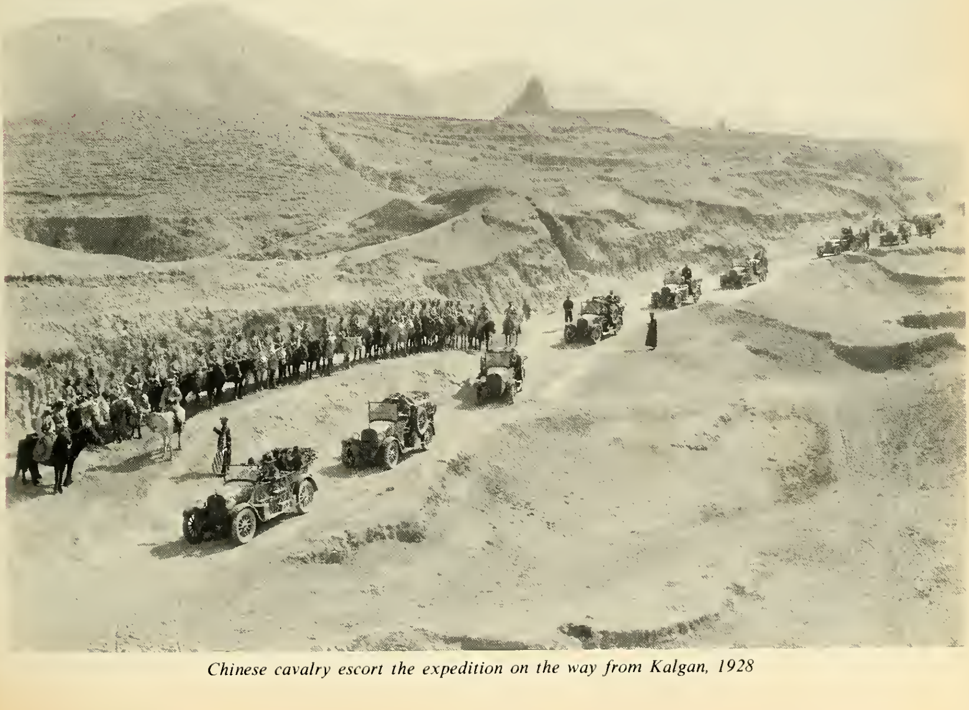
The Central Asiatic Expedition was fortunate in being able to continue its work in 1930, after a year's delay due to Chinese objections. Official sanction, however, was not finally obtained until the middle of May, and we could not leave for Mongolia until the 20th of that month—just five weeks later than in previous years.

A consultation decided us to send the camels to the place just south of the Outer Mongolian frontier, where we had discovered a jaw of the extraordinary shovel-tusked mastodon in the autumn of 1928. We had only partly explored that region and we hoped for great things in a more intensive study.

Some two or three million years ago in the Pleistocene



*The expedition's camel caravan crossing the Mongolian dunes, 1925*



*Chinese cavalry escort the expedition on the way from Kalgan, 1928*

*Wolf Camp, Mongolia, July 1930*

period, a great lake had occupied this part of Mongolia. The shore-line was clearly delineated by masses of fresh-water shells. It was probable that along the borders of this inland sea there had been quicksand bogs and muddy river bottoms in those far distant days when the shovel-tusked mastodon roamed the savannahs of Mongolia. Bogs and quicksands acted as traps then just as they do today. They are one of the most fruitful sources of well-preserved fossils and we began an intensive exploration of the lake shore.

We pitched our tents on a flat plain overlooking a great basin, cut and slashed by the knives of wind and frost and rain into a thousand gaping wounds. Behind us stretched a plateau which flowed away in great sweeping billows, a seemingly flat expanse. It was only when a horse or a running antelope disappeared suddenly from the eye that one could realize that the plain was not as flat as the top of a table. We knew from previous explorations that this was a dangerous place, because for many miles in every direction it was a waterless expanse. Mongols could not live there except in winter; it was inhabited only by antelopes, wolves, and desert birds. We named our camping place Wolf Camp, because, during two months' stay, we shot thirteen of these

*Platybelodon quarry five miles south of Wolf Camp, July 1930*

*Fossils laid out on the floor of the laboratory at the Peking headquarters, 1930*

marauders which preyed upon the sheep and goats of the Mongols, in a village grouped about a marshy pond eight miles away on the lowlands.

Just below the tents on a narrow promontory, we discovered many outcrops of bones. When the deposit was opened, the skulls, jaws, and skeletal parts of baby mastodons far out-numbered all other animals. Evidently this had been a bog near the shore of the lake. Mother shovel-tusked mastodons with their babies had come here to drink or feed. The mud was comparatively shallow and, although both the adults and young doubtless became mired, the mothers, because of their superior strength, were able to extricate themselves and sometimes get out their babies also. But others were not so fortunate and many of them had been left to die. The crowning specimen was the jaw and part of the skull of an unborn baby. It lay in the pelvic bones of an adult female, the only adult which we found in the deposit. Albert Thomson delivered the child with Walter Granger as consulting physician, while the rest of us in the clinic amused ourselves by calling them such insulting names as "palaeontological midwives."

The most spectacular discovery of the year was made six miles to the south of Wolf Camp by Père Teilhard de Chardin. In an amphitheater, marked by a shining dome of pure white marl, hundreds of fossils were exposed upon the surface but all in a very restricted locality. Granger and Thomson, with their assistants, opened the deposit. They found great numbers of shovel-tusked mastodon jaws, skulls, and bones lying in a heterogeneous mass like a heap of giant jack straws. For six weeks the men worked in this one spot, taking out the most priceless specimens day after day. I used to sit on the edge of the escarpment just above them, drifting in imagination back to those past days when the waters of a beautiful lake filled the enormous basin. Where we worked, there had been a bay on the edge of which was a deep well of soft sticky mud. Probably it was covered by three or four feet of water on which grew a luxuriant mass of tubers and succulent aquatic plants—the favorite food of the shovel-tusked mastodon. One of these gigantic beasts plowed its way slowly along the shore of the bay, dredging up masses of trailing vegetation in its great spoon-shaped jaw. Then with its trunk or mobile lips the beast delicately selected choice bits and pushed them far back into its huge mouth to be masticated by the molar teeth. The plants floating over the death trap of mud enticed the mastodon farther and farther into the water. Suddenly it found that it could not withdraw its feet. Struggling madly in the grip of the clinging mud, it sank lower and lower until the water covered its head and the last struggles were those of a drowning beast. The trap remained baited and still other mastodons were lured into the well of death. Their huge bodies sank upon those that had gone before, until the pit was choked with masses of decomposing flesh. Eventually the lake dried up, but the bones remained entombed until we came to open the grave on that brilliant day in 1930. Seventeen great spoon-shaped jaws were taken out of this single deposit. With those obtained from the "baby pit," the Museum has a superb age series representing almost every stage in growth from the unborn young to the adult bulls with jaws five and one-half feet long. This age series is only rivaled by that of the dino-

## THE MOTOR TRUCK IN CENTRAL ASIA

By ROY CHAPMAN ANDREWS

I remember once when we were returning to Kalgan from Urga, the capital of Mongolia, we discovered that the oil of our motor had all leaked out of the cans. It was impossible to go much farther and we were debating what to do. As our car swung over the summit of a rise, we saw the white tent and grazing camels of an enormous caravan. Of course, Mongols would have mutton fat and why not use that for oil! The caravan leader assured us that he had fat in plenty and in ten minutes a great pot of it was warming over the fire.

We poured it into the motor and proceeded merrily on our way. But there was one serious obstacle to our enjoyment of that ride. We had had very little food for some time and were very hungry. When the engine began to warm, a most tantalizing odor of roast lamb arose from the car! Shortly, I even imagined that I could smell mint sauce.

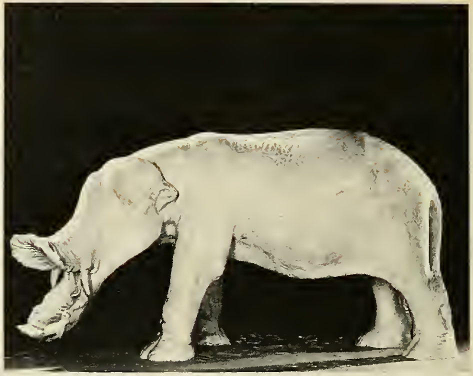
Once again we were without cup grease for the cars and Mrs. Andrews sacrificed all the cold cream and vaseline which she had prepared for a summer in the field. Mongol cheese, too, was substituted with good results.

saur *Protoceratops*, which demonstrates its growth from the egg up to the very old males.

The expedition spent two months at Wolf Camp, busy every moment on new and interesting discoveries. We might have remained all summer at this one site, for half a dozen other places were located which doubtless would have proved as rich as those tombs we had already opened. It is only in such deposits and in the river drift of ancient stream beds that we may hope to find the remains of primitive human types.

The summer's work indicated that this entire region was so rich and important that several years of additional work were highly desirable. Upon cabled instructions from President Osborn, I went to Peking on the 1st of September to open negotiations with the Committee for the Preservation of Ancient Objects. Mackenzie Young and I with one Chinese, Liu Shi-ku, drove down in two cars. During the summer the region had been remarkably clear of bandits, but it had been rumored that great quantities of opium were to be brought in from the west. This rich cargo had drawn bandits like flies to honey. A hundred and twenty miles from Kalgan the brother of one of our Mongols, Bato, told us that two Chinese cars had been robbed the night before and two men killed by thirty or forty brigands. He supposed that they were still there awaiting other victims and advised us not to go on. Mack and I, however, were heavily armed and decided to go through. Either the bandits had left or they were reluctant to attack us, because we reached Kalgan without a shot being fired. A week later, Mack returned accompanied only by Liu who drove the second car. Before he left Peking I had a strong presentiment that he would have trouble. It had been raining hard and the trail was very slippery. A hundred and ten miles from Kalgan a Mongol child ran out to the trail and told them that bandits had just stopped a caravan five miles away. Mack had either to turn back to Kalgan or else proceed and take his chance. He decided to go on. At a tiny mud-walled house in the bottom of a valley, he saw the brigands dressed in Chinese soldier uniforms robbing a caravan of carts. He drove on as fast as possible, but when his car was opposite the house, the robbers opened fire with Luger pistols from behind a mud wall. Slowing up a little, Mack took a snap shot at one man who was doing the best shooting. His bullet struck a stone, went to pieces, and took off part of the bandit's face. Another struck a second man in the shoulder. A little farther on were a dozen robbers standing by their horses. They opened fire with rifles as Mack went by and then started to mount their ponies. He killed a horse and this so discouraged the brigands that they galloped away. It had been a neat little fight and the bandits had been taught a pretty severe lesson. Fortunately, neither Mack nor Liu were hit.

*Excavating turtle skeletons near Camp Margetts, September 1930*

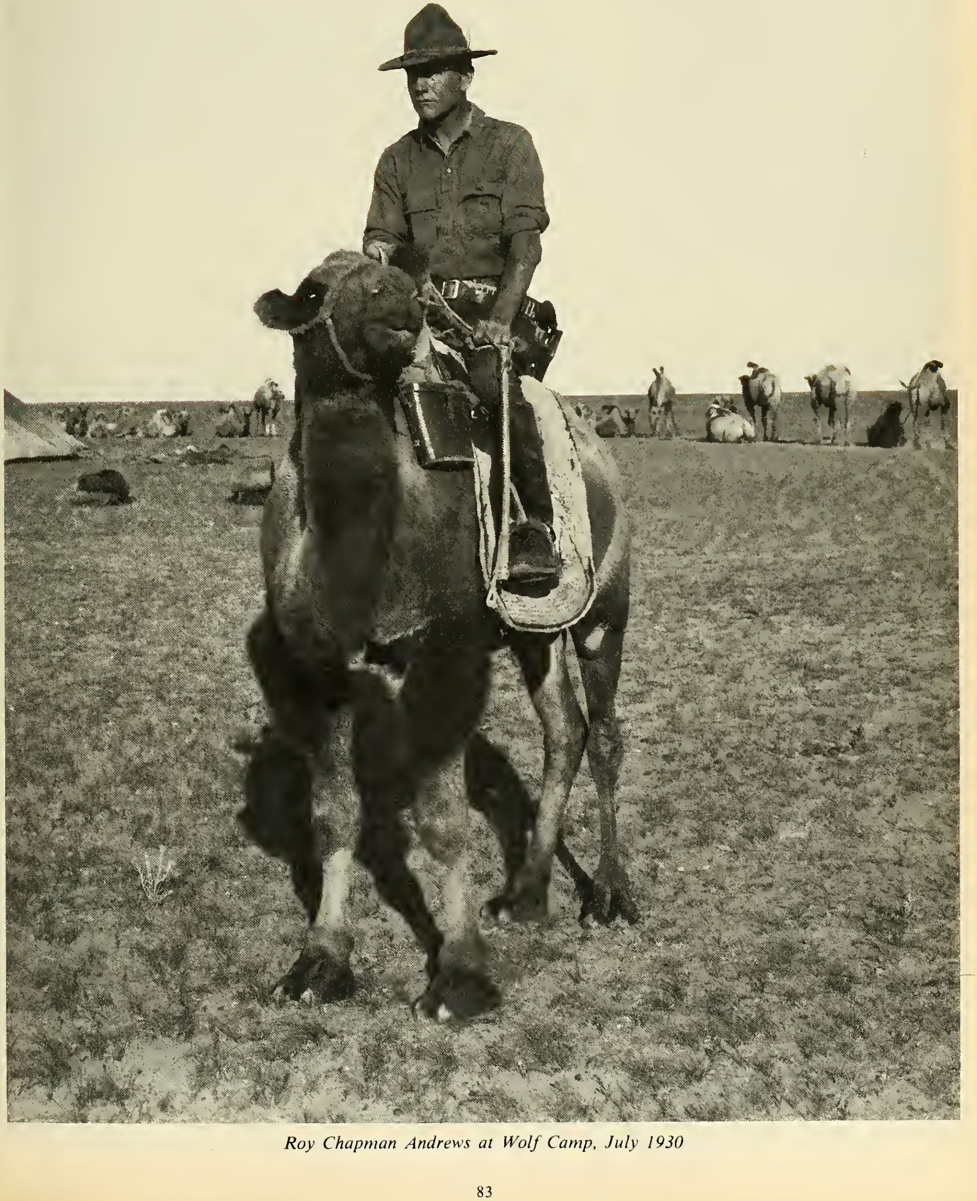


*Model of the Platybelodon, or shovel-tusked mastodon*

The whole Expedition returned a month later. Two days after they had reached Kalgan the entire region was taken over by bandits and all traffic on the plateau ceased. Had our people been delayed, the consequences would have been serious. It was only another evidence of the good luck which has been a constant factor in the success of the Central Asiatic Expeditions. The camels carrying our collections were met at a village thirty-four miles from Kalgan by Young and Liu and the fossils brought safely to Peking.

I cannot speak too highly of the courage and loyalty of every man, native and foreign, of the Expedition's staff. Through their splendid efforts the season's work netted the largest collection of any year in Mongolia. Ninety-one cases of fossils were obtained. We all feel that in scientific importance, as well as in bulk, this year's collections from Eastern Mongolia will equal if not surpass those of any previous season.

During all of the past years of our exploration, we have worked in central and western Mongolia where late Tertiary strata appear not to exist. Although we have opened a new volume in the history of the earth, the proper conditions under which human remains could be found were only discovered last year. It would be a scientific tragedy if lack of sympathy in China forces us to terminate our work.



*Roy Chapman Andrews at Wolf Camp, July 1930*

# MY LIFE AS A NATURALIST

BY THEODORE ROOSEVELT

I DON'T suppose that most men can tell why their minds are attracted to certain studies any more than why their tastes are attracted by certain fruits. Certainly, I can no more explain why I like "natural history" than why I like California canned peaches; nor why I do not care for that enormous brand of natural history which deals with invertebrates any more than why I do not care for brandied peaches. All I can say is that almost as soon as I began to read at all I began to like to read about the natural history of beasts and birds and the more formidable or interesting reptiles and fishes.

In the broader field, I sat at the feet of Darwin and Huxley; and studied the large volumes in which Marsh's and Leidy's palaeontological studies were embalmed, with a devotion that was usually attended by a dreary lack of reward—what would I not have given fifty years ago for a writer like Henry Fairfield Osborn, for some scientist who realized that intelligent laymen need a guide capable of building before their eyes the life that was, instead of merely cataloguing the fragments of the death that is.

I was a very nearsighted small boy, and did not even know that my eyes were not normal until I was fourteen; and so my field studies up to that period were even more worthless than those of the average boy who "collects" natural history specimens much as he collects stamps. I studied books industriously but nature only so far as could be compassed by a molelike vision; triumphs consisted in such things as bringing home and raising—by the aid of milk and a syringe—a family of very young gray squirrels, in fruitlessly endeavoring to tame an excessively unamiable woodchuck, and in making friends with a gentle, pretty, trustful white-footed mouse which reared her family in an empty flower pot. In order to attract my attention birds had to be as conspicuous as bobolinks or else had to perform feats such as I remember the barn swallows of my neighborhood once performed, when they assembled for the migration alongside our house and because of some freak of bewilderment swarmed in through the windows and clung helplessly to the curtains, the furniture, and even to our clothes.

Just before my fourteenth birthday my father—then a trustee of the American Museum of Natural History—started me on my rather mothlike career as a naturalist by giving me a pair of spectacles, a French pin-fire double-barreled shotgun—and lessons in stuffing birds, provided by Mr. John G. Bell, a professional taxidermist and collector who had accompanied Audubon on his trip to the then "Far West."

With my spectacles, my pin-fire gun, and my clumsy industry in skinning "specimens," I passed the winter of '72–73 in Egypt and Palestine, being then fourteen years old. My collections showed nothing but enthusiasm on my part. I got no bird of any unusual scientific value. My observations were as valueless as my collections save on just one small point; and this point is of interest only as showing, not my own power of observation, but the ability of good men to fail to observe or record the seemingly self-evident.

Two species of chats—Old World chats, of course, which have nothing in common with our queer warbler of the same name—were common along the edges of the desert. One species was a boldly pied black and white bird, the other was colored above much like the desert sand, so that when it crouched it was hard to see. I found that the strikingly conspicuous chat never tried to hide, was very much on the alert, and was sure to attract attention when a long way off; whereas the chat whose upper color harmonized with its surroundings usually sought to escape observation by crouching motionless. These facts were obvious even to a dull-sighted, not particularly observant boy; they were essential features in the comparison between and in the study of the life histories of the two birds. Yet neither of the two books in my possession dealing with Egyptian birds so much as hinted at them.

I think it was my observation of these, and a few similar facts, which prevented my yielding to the craze that fifteen or twenty years ago became an obsession with certain otherwise good men—the belief that all animals were protectively colored when in their natural surroundings. That this simply wasn't true was shown by a moment's thought of these two chats; no rational man could doubt that one was revealingly and the other concealingly colored; and each was an example of what was true in thousands of other cases. Moreover, the incident showed the only, and very mild, merit which I ever developed as a "faunal naturalist." I never grew to have keen powers of observation. But whatever I did see I saw truly, and I was fairly apt to understand what it meant.

After returning to this country and until I was halfway through college, I continued to observe and collect in the fashion of the ordinary boy who is interested in natural history. During the years when I "collected specimens" at Oyster Bay or in the north woods, my contributions to original research were of minimum worth. I lived in a region zoölogically so well known that the obvious facts had all been set forth already, and as I lacked the power to find out the things that were not ob-

*TR in Africa*

vious, my work merely paralleled the similar work of hundreds of other young collectors who had a very good time but who made no particular addition to the sum of human knowledge.

Among my boy friends who cared for ornithology was a fine and manly young fellow, Fred Osborn, the brother of Henry Fairfield Osborn. He was drowned, in his gallant youth, forty years ago; but he comes as vividly before my eyes now as if he were still alive. One cold and snowy winter I spent a day with him at his father's house at Garrison-on-the-Hudson. Numerous northern birds, which in our eyes were notable rarities, had come down with the hard weather. I spied a flock of crossbills in a pine, fired, and excitedly rushed forward. A twig caught my spectacles and snapped them I knew not where. But dim though my vision was, I could still make out the red birds lying on the snow; and to me they were treasures of such importance that I abandoned all thought of my glasses and began a nearsighted hunt for my quarry. By the time I had picked up the last crossbill I found that I had lost all trace of my glasses; my day's sport—or scientific endeavor, whatever you choose to call it—came to an abrupt end; and as a result of the lesson I never again in my life went out shooting, whether after sparrows or elephants, without a spare pair of spectacles in my pocket. After some ranch experiences I had my spectacle cases made of steel; and it was one of these steel spectacle cases which saved my life in after years when a man shot into me in Milwaukee.

While in Harvard I was among those who joined in forming the Nuttall Club, which I believe afterward became one of the parent sources of the American Ornithologists' Union.

The Harvard of that day was passing through a phase of biological study which was shaped by the belief that German university methods were the only ones worthy of copy, and by the proper admiration for the younger Agassiz, whose interest was mainly in the lower forms of marine life. Accordingly it was the accepted doctrine that a biologist—the word "naturalist" was eschewed as archaic—was to work toward the ideal of becoming a section-cutter of tissue, who spent his time studying this tissue, and low marine organisms, under the microscope. Such work was excellent; but it covered a very small part of the biological field; and not only was there no encouragement for the work of the field naturalist, the faunal naturalist, but this work was positively discouraged, and was treated as of negligible value. The effect of this attitude, common at that time to all our colleges, was detrimental to one very important side of natural history research. The admirable work of the microscopist had no attraction for me, nor was I fitted for it; I grew even more interested in other forms of work than in the work of a faunal naturalist; and I abandoned all thought of making the study of my science my life interest.

But I never lost a real interest in natural history; and I very keenly regret that at certain times I did not display this interest in more practical fashion. Thus, for the dozen years beginning with 1883, I spent much of my time on the Little Missouri, where big game was then plentiful. Most big game hunters never learn anything about the game except how to kill it; and most naturalists never observe it at all. Therefore a large amount of important and rather obvious facts remains unobserved or inaccurately observed until the species becomes extinct. But I vaguely supposed that the obvious facts were known; and I let most of the opportunities pass by. Even so, many of my observations of the bighorns, white goats, prong-bucks, deer, wapiti, and occasional observations on some of the other beasts, such as black-footed ferrets, were of value.

To illustrate what I mean as "obvious" facts which nevertheless are of real value I shall instance the cougar. In the winter of 1910 I made a cougar hunt with hounds spending about five weeks in the mountains of northwestern Colorado. At that time the cougar had been seemingly well known to hunters, settlers, naturalists, and novelists for more than a century; and yet it was actually impossible to get trustworthy testimony on such elementary points as, for instance, whether the male and female mated permanently, or at least until the young were reared (like foxes and wolves), and whether the animal caught its prey by rambling and stalking or, as was frequently asserted, by lying in wait on the branches of a tree. The facts I saw and observed during our five weeks' hunt in the snow needed only the simplest powers of observation and of deduction from observation.

In South America I made observations of a certain value on some of the strange creatures we met, but the trip was primarily one of exploration. In Africa, however, we really did some good work in natural history. Many of my observations were set forth in my book *African Game Trails;* and I have always felt that the book which Edmund Heller and I jointly wrote, the *Life Histories of African Game Animals,* was a serious and worth-while contribution to science. Here again, this contribution, so far as I was concerned, consisted chiefly in seeing, recording, and interpreting facts which were really obvious, but to which observers hitherto had been blind, or which they had misinterpreted partly because sportsmen seemed incapable of seeing anything except as a trophy, partly because stay-at-home systematists never saw anything at all except skins and skulls which enabled them to give Latin names to new "species" or "sub-species," partly because collectors had collected birds and beasts in precisely the spirit in which other collectors assembled postage stamps.

I do not think there is much else for me to say about my anything but important work as a naturalist. But perhaps I may say further that while my interest in natural history has added very little to my sum of achievement, it has added immeasurably to my sum of enjoyment in life.

---

Theodore Roosevelt, president of the United States from 1901 to 1909, died less than one year following publication of this article. To perpetuate his life and work, the New York State Theodore Roosevelt Memorial Building was dedicated in 1936, and its administration delegated to the trustees of the American Museum of Natural History. The building, which serves as the Museum's principal entrance, bears murals and other decorations commemorating Roosevelt's character and accomplishments.

# "TURNING KOGMOLLIK" FOR SCIENCE

Experiences of the Museum's Arctic Expedition

THERE could be no more simply told story of hardship, of high hopes made futile by storm and illness than that recorded in the latest letters from the Museum's Arctic Expedition. The past winter will long be remembered as the "hard times" winter by the two expedition leaders, Messrs. V. Stefánsson and R. M. Anderson, "turned Kogmollik" in the cause of science—"to turn Kogmollik" meaning to join forces with the Kogmollik Eskimos of the Mackenzie delta and eastward, dressing as they do and wandering with them to get a living from the country.

Any man who goes into the Arctics expects the possibility of having to face starvation, unless he takes a ship. It is impossible to carry with dog team or small boat enough to serve for more than a short journey; and if at the end of the journey, game proves scarce or wandering bands of Eskimos cannot be located, retreat from the difficult situation becomes problematic. In such straits Eskimos sometimes have to sacrifice their dogs; but unless worst comes to worst, they take such an adventure as a matter for joking and with whetted courage push on, perhaps in the face of a blizzard and through deep snows. The explanation of the Eskimo's cheerful view of the matter lies largely in his trust in the hospitality of his fellow Eskimos. For in Eskimo character there has evolved great unselfishness and in Eskimo tribal life a rare communism, passing strange and contradictory as it may seem that this should have taken place in a land of cold and privation, opposed to the selfishness and cruelty of most peoples of southern countries where there are physical comfort and plenty. A chief in the Arctics is not appointed or chosen, nor does he inherit his title. He attains it from a reputation for hospitality.

The Stefánsson-Anderson Expedition differs essentially from ordinary Arctic ventures in that whereas it is usual to carry along everything that the party is expected to need during its stay in the field, in this instance, little in the way of food, clothing or house materials was taken. This was the original plan, since the primary aim of the expedition is ethnological. How can a white man become familiar with the real life of primitive peoples, with their language, folk lore and songs, customs, beliefs and ambitions, except by living with them in their houses and as they do? Therefore, the leaders of the Arctic Expedition dress in Eskimo clothes, which weigh no more than a spring suit yet "allow one to sit comfortably on a block of snow, with back to the wind, fishing through a hole in the ice, the temperature being –50° Fahrenheit, and to feel the cold nowhere but on the face." They eat Eskimo food also, a great acquirement for a white man, and report that since the first month's difficulties they relish all—raw frozen fish, eaten as one would eat corn from the cob, boiled fish without salt, taken with the fingers, even the Eskimo delicacy of boiled fish heads, and, of course, seal oil, whale blubber and deer meat.

The Arctic Expedition left New York in May, 1908, to make a scientific study of little-known Eskimos, especially those tribes east of the Mackenzie River, and to obtain, of course, as much material as possible to illustrate Eskimo life and customs. Secondarily, it is to carry on a zoölogical survey, procuring collections of mammals, birds and fish, this work being in the hands of Dr. Anderson.

Although the desire was to go directly to the eastern Eskimo tribes, the final arrangements sent the expedition west to the Colville River area with the idea of returning eastward by whaling ship. The latter plan ingloriously miscarried owing to the fact that no whaling vessel visited the region during the whole season, the first time such a thing had occurred during the forty years since ships began to visit there regularly. Thus the expedition was forced to winter in the lower Colville region.

Now it happens that the Colville, which is very poor in game, is not the place one would choose in which to spend a winter. The year before both dogs and Eskimos had starved to death there and many families had moved out. But the winter proved less difficult than had been feared; spring came and the main energies of the summer of 1909 were spent in getting eastward, with much time lost waiting for whalers which never came. Finally Mr. Stefánsson succeeded in getting as far east as Cape Parry, near enough to the Coppermine River area for a dash there at the opening of the spring of 1910—if the intervening winter could be successfully passed. It is this winter in the Cape Parry district that has proved the "hard times" winter for the expedition, set forth in the narrative of recent letters.

We landed, Nat-ku-tji-ak, his wife Pan-ni-gáb-luk and I, August 31, by the stranded wreck of the steam whaler "Alexander," lost here in the summer of 1906, ten miles east of Cape Parry. Our first object was to find deer, as we were insufficiently clothed for the winter and had on hand provisions for about two months only. After hunting inland in vain two days, we decided to store most of our stuff in an old house built by some Eskimos who pillaged the "Alexander," then proceed to Langton Bay to look for deer.

As soon as possible we began edging southwest along the coast, but it was slow work. Paddling a big umiak is slow work under any condition for three people. A few days of southwest gales would be separated from a few more days of southwest gales by perhaps a half day of calm, but never a breath of fair or land wind. Unfortunately for us we happened to have with us a map of the coast. When on September 7 we came to a bight in the shoreline which corresponds

Adm. Robert E. Peary, the first man to reach the North Pole, called Vilhajalmur Stefansson "the last of the old school" of Arctic explorers; "the worker with the dog and the sledge."

Actually, the "old school" to which Stefansson belonged was that of the explorer as showman-celebrity. Unfortunately, polar wastes proved ill-suited grounds for testing media myths. The Norwegian explorer Roald Amundsen warned that "certain death awaits" anyone misled by Stefansson's talk of the "friendly Arctic."

Certain death awaited Stefansson's 1913–18 Arctic expedition. William Laird McKinley, the last survivor, recently published a detailed account of this tragic venture. The expedition was ill conceived and carelessly planned. The ships weren't properly modified. Their cargoes weren't sensibly divided. The pemmican lacked fat. The staff were untrained in Arctic survival. There was absolutely no leadership. With the main ship, *Karluk*, ice locked and endangered, Stefansson left to go hunting.

When he returned, his ship was gone. It drifted west with the ice, then sank. Most of its complement of twenty-five (including an Eskimo woman and two children) reached Wrangel Island. From there the captain and an Eskimo crossed 200 miles of ice to Siberia, then traveled 500 miles along the coast to East Cape, where they sought help. A relief party, six months later, found eleven dead. Eight froze. Two starved. One killed himself.

Stefansson, accepting no blame, wrote an inaccurate and uncharitable account of these events. To prove himself right, he organized another expedition: four men and an Eskimo girl were left on Wrangel with provisions for six months to last them a possible two years. Only the girl survived.

Yet Stefansson became, in the press, *the* name in Arctic exploration. No more. Those headlines are now forgotten. Who now remembers Stefansson's report of a race of "Blond Eskimos"? His tales of survival by ingenuity are questioned. He was a good hunter, but he lived off the people as much as off the land. On one occasion, when he wrote of self-sufficiency, a companion, in his diary, wrote of "two sleds heavily laden with 200 pounds of whale meat and 400 frozen fish . . . purchased from Arlook."

Stefansson was a likable man and undoubtedly brave. He was also a good writer. But while he entertained the public, a number of quiet scientists began to explore this last great unknown. They treated northern problems practically, taking no unnecessary chances. Their goal was the advancement of knowledge.

Surely the greatest among them was Knud Rasmussen, who traveled across Arctic America from Greeland to Siberia, without mishap. This part-Danish, part-Eskimo ethnologist combined field life with genius. Today the world knows the Eskimos through his books, not because the press proclaimed him, but because he recorded a world more wondrous than anything conceived by "news makers." *Edmund Carpenter*

*An authority on the art and culture of the Arctic, Edmund Carpenter teaches anthropology at the New School for Social Research and communications at New York University. His most recent article for Natural History was published in February 1980.*

excellently with one on the map into which the map makers show that a large river empties, we concluded we had reached this river, R. la Roncière. The formation of the coast simulated well the mouth of a large river. We all agreed that the river must have trees, or at least large willows, as all good-sized rivers do, which would mean game, and it seemed advisable to ascend it. The beach was covered with small spruce drift trees which promised well. I made an entry in my diary to the effect that "R. la Roncière" differed from most Arctic rivers in that the Lord had put it in the same place as had pleased the map makers.

We ascended and found, sure enough, a river—small, it is true, but we took it for one of the numerous delta channels of a large stream. We went for about five miles farther and came to a small lake. We know now that "R. la Roncière" does not exist. It took us two days of fair weather to get back to the open sea again, and we finally reached Langton Bay September 13.

At Langton Bay, Mr. Stefánsson and the Eskimos hunted with little success. This was unfortunate because all were short of deerskins. Each person in the Arctics needs at least six deerskins for clothes and three for bedding; in fact a total of nine skins is rather short allowance. Also, by the end of October, considerable anxiety began to be felt concerning the whereabouts of Dr. Anderson's party. Eventually Mr. Stefánsson and his Eskimo started out to find him, first building a log house with an open fireplace where the Eskimo woman could stay to protect a cache of twenty-two deer. Travelling was difficult but they reached the coast fifty miles west from Langton Bay by November 18. Here they found on the beach an old whale carcass, probably four years old, and spent a day getting a sled-load of blubber before proceeding. They had gone on only a day's journey when they were rejoiced to meet Dr. Anderson with his six Eskimo assistants. The whole party returned to the beach where the frozen whale was and spent the day getting another load of blubber and in talking over the situation.

Dr. Anderson had been traveling under unusual difficulties because he had a large party of assistants to make possible the transportation of supplies and collecting equipment. He says respecting this, "Turning Kogmollik has its disadvantages as well as its advantages. Alone I could shoot more game than I drew out of the pot and still have much leisure time for other work. There was certain work to be done, however, which I could not handle alone and diplomatic reasons compelled me to become a communist out and out. This meant a hand to mouth existence for a time with so many to be fed, some worry, and much hard work, but brought my boat and goods to the place where they had to be."

The matter of assistants in the Arctics is a large problem. To hire an Eskimo means that his family also must be fed and carried along with the expedition. Captain Roald Amundsen is of the opinion that outside of the scientific staff of an expedition Eskimos should best be depended on for all work, his chief reason being not the greater resistance of the Eskimo physically to northern hardships, although that is true also, but that the Eskimo does not get homesick and is not continually downhearted. The Eskimo's disposition is such that whether he be cold, hungry or in danger he seldom becomes dispirited or sulky. Commander Peary has always spoken in favor of Eskimo assistants and has always shown his personal preference in being accompanied by them on his dashes for the Pole. Mr. Stefánsson who had previously spent a year with the uncivilized Eskimo agreed with this opinion in favor of the Eskimo and the Museum's Arctic Expedition was planned accordingly. He reports, however, a wonderful change in the Eskimos as

regards pay for services since he was at the Mackenzie delta in 1906. "Then they knew little about money and one could hardly pay for anything. He might make gifts, but pay was never asked and if offered needed explaining by the statement that white men always pay for food and work in their own country. So great is the change that now an Eskimo seldom remains permanently satisfied with the most liberal pay for services."

While the reunited divisions of the expedition worked getting a store of blubber, the leaders reviewed the past and carefully studied the future. One thing was certain, they must have the traps and ammunition that had been left perforce in the old house beside the wrecked "Alexander." Black and silver fox had recently been seen, black fox with a value from six hundred to a thousand dollars per skin. Besides there could be no more opportune time to get the things necessary for the Coppermine trip which would begin in the spring as soon as the sun came back. It was, therefore, decided that they should separate once again, and that Dr. Anderson with two Eskimos and ten dogs should go at once to the "Alexander." The day they separated was one of the worst of the year, –35° with a southwest blizzard. Going with the storm, Dr. Anderson could proceed; going in the face of the gale, Mr. Stefánsson's dogs refused to work, and his party was forced to wait till the storm abated. At last they started, six people with two days' provisions, and after fifteen days of struggle they got back to the log house where they had left the Eskimo woman in charge of the cache. Nothing could be more graphic than Mr. Stefánsson's description of these fifteen days:

> On the whole trip we killed five ptarmigan and not a single rabbit, though one of us hunted each bank all the way up. The sun was gone and so the daylight was meagre, besides it blew a blizzard every day. The whale tongue was very bad eating, it had little to it but dry fibres and was strongly impregnated with sea salts (other than NaCl). When we had finished this we were really better off for the stuff seemed to make us sick. We then ate sealskin, some deerskin we had along for sole leather and our snowshoe lashings, in fact every edible thing except clothes. Fortunately we had seal oil. With about a cupful of oil a day one does not feel in the least hungry but lazy, sleepy and weak. All of us found it a little difficult to take the oil straight. We soaked it up in tea leaves, deerskin with long hair on it and ptarmigan feathers.

Before they reached the end of these fifteen days some of the Eskimos were taken sick, and did not recover for weeks. These were indeed most discouraging times. Mr. Stefánsson was not able to go far from the camp because of the sick Eskimos, there were seven people and six dogs to feed, meaning a consumption of rather more than a deer per day, while there was no light but dim twilight for hunting, and every southeast wind brought fog, every southwest wind, a blizzard. To add to other causes for depression all were feeding wholly on lean meat in Arctic cold where health and spirits depend on the presence of fat in the food. Also it was at this time that the oil for lights gave out:

> At this time we had left only about a quart of oil, which was soon gone and we were without lamplight all the time the sun was away. This was especially inconvenient for the women, as sewing in the dark is difficult. There was more than once a whole week, too, when I made no entry in my diary because I could not see. One could write for about two hours at noon, but I was usually hunting at that time, always starting out before daybreak.
>
> In addition, we were getting badly worried over the non-arrival of Anderson and his party. They should have been home by Christmas. We were especially afraid that on the very day they left us in the blizzard they might have ventured too far off shore on the ice and have been carried with

it to sea. The sick Eskimos were growing despondent. I used to see deer almost every clear day (there was fog or blizzard two days out of three) but on the clear days it was so absolutely breathlessly calm that deer could hear you and you could hear them from a quarter to a half mile away. I therefore never got a shot at them. An Eskimo always looks upon such protracted ill luck as caused supernaturally. Taboos had been violated. They knew I had eaten deermeat the day I killed a wolf, but worse than that they knew of more than one case of my breaking the Sabbath. They were therefore certain they should never be able to get any deer. One day, however, I shot a fawn. This seemed to break the spell to the notion of the Eskimos.

In early January lack of food made some sort of a venture necessary, so a start was made for Langton Bay. Reaching the old house by the wreck of the "Alexander," they were astounded to find Dr. Anderson and one of his Eskimos there, recovering from pneumonia. Fortunately flour had been among the supplies left at the house or the men never could have lived through. Polar bears had broken in and devoured four boxes (500 lbs.) of whale blubber, two slabs of bacon, spilled a ten-gallon can of alcohol and "knocked things about generally"; but the flour they had not disturbed.

The letters report that in March all were "in fit condition, showing no serious after-effects," and that Mr. Stefánsson was expecting to start with his party during the first week in April for the Coppermine.

The expedition is planning to come out of the field soon, and great interest at the Museum attaches to the time when the full results of the work will be known. Making a zoölogical survey in the Arctics is a peculiarly difficult task due largely to problems of transportation of outfit and accumulating specimens; and the collections with duplicate series which the expedition reports will be of great scientific value. With the close of this expedition, Mr. Stefánsson will have five years' knowledge of the Eskimo. He has accomplished much in getting records of songs and short tales, working to ascertain definitely the presence and variations of certain folk tales throughout the tribes. He has complete lists of words used by the Shamans in ceremonials; and he has a large series of head measurements and many photographs. All results of the expedition will possess unusual value, representing as they do, work accomplished in spite of the almost insuperable obstacles set by the Arctic winter and by the necessity of "turning Kogmollik."

---

Stefansson left Langton Bay on April 21, 1910, in search of unknown Eskimo groups of the Coronation Gulf–Victoria Island region. For a trip that he expected might last a year, he went with three Eskimos, six dogs, and enough food for two weeks—like his native companions, he had become adept at living off the land.

On May 13, on the ice of Dolphin and Union Strait, Stefansson's party came upon Eskimos who had never seen white men, who lived as their ancestors had lived since time immemorial. "Here were not remains of the Stone Age, but the Stone Age itself, men and women, very human, entirely friendly, who welcomed us to their homes and bade us stay."

Even more startling, after crossing a portion of Victoria Island to Prince Albert Sound, Stefansson met Eskimos with a "light complexion [and] fair beards . . . I knew I was standing face to face with an important scientific discovery." He theorized that these people might be descendants of Greenland's "lost" Norse settlers. Upon his arrival in Seattle in the fall of 1912 he gave an interview in which, full of enthusiasm but somewhat injudiciously, he dwelt at length on his discovery of "blond Eskimos." The press loved the story, headlined it, embroidered it. Stefansson gained instant popular fame, but his scientific reputation was slightly tarnished. "The most palpable nonsense that ever came from the North," was the scathing comment of the famous explorer Roald Amundsen. The ensuing wrangle overshadowed to some extent the enormous achievements of the expedition, which with scant supplies, had spent more than four years in the Arctic and had returned with a wealth of scientific information and over 20,000 specimens.

On his way to the Arctic in 1908, along the Athabasca River, Stefansson noticed tar "which here and there trickled down the cut-banks of the river." Natural gas flared in the wilderness. To Stefansson it was "the torch of Science lighting the way of civilization and economic development to the realms of the unknown North." The Alberta tar sands are expected to yield 550,000 barrels of oil daily by 1985. Diamond Jenness, ethnologist on Stefansson's next, last, and greatest expedition (1913–1918) heard from natives on the Alaska coast about a "strange lake of 'pitch' . . . which poisoned any bird or animal that drank from it." Now a giant pipeline carries oil from this region across Alaska.

When Stefansson discovered the long-isolated Copper Eskimos, he found them to be a people who knew no illness and who were "more nearly satisfied with their condition" than anyone he had ever met, and he feared they would be "crushed by civilization's juggernaut." Within "ten years of our departure," wrote Diamond Jenness, "one-third of them had been swept away by influenza." And many of the survivors were suffering from advanced tuberculosis. Today, the land Stefansson knew so well is empty. Most Eskimos live in a few large settlements, in government-built three-bedroom houses. They watch television programs brought to them by satellite.

But the huge warehouses and the great community hall built by nineteenth-century whalers still stand. In the Beaufort Sea, which Stefansson crossed by dog team, giant dredges build artificial islands and drills probe for oil and gas. At Cape Parry, which he reached with so much trouble in August 1909, there is now a Distant Early Warning Line station. Ten miles away, the boilers of the whaler *Alexander*, wrecked in 1906, lie on the beach. And at Holman on Victoria Island, just north of Prince Albert Sound where Stefansson and Nat-ku-tji-ak first met the blond Eskimos, lives Jimmy Memogana. Now in his sixties, he is considered to be one of the best hunters and trappers in the settlement, just like his step-father, Nat-ku-tji-ak, whom Stefansson called "my mainstay" and "the best of all Eskimo hunters that I have known." *Fred Bruemmer*

# A CHAPTER OF HISTORY AND NATURAL HISTORY IN OLD NEW YORK

### By GEORGE BIRD GRINNELL

THE wild life of New York City is for the most part transient; we see only birds of passage. During the migrations, native birds sometimes drop down into parks, back yards, or other open spaces, and are recognized by the passers-by as different from the English sparrow. People who know birds occasionally recognize thrushes, blackbirds, warblers, and even scarlet tanagers in the smaller parks; and sometimes other birds appear, as when a few years ago I saw a woodcock in Trinity Churchyard at Rector Street, and still longer ago, one in Union Square, which, when startled, flew straight east through 16th Street to alight no doubt in Stuyvesant Square.

The larger parks, like Central Park and Bronx and Prospect parks, permit birds to live under more or less natural conditions, and shelter, besides the birds, a few mammals—two or three species of squirrels, cottontail rabbits, and other lesser creatures. A few years ago a brood of wild black ducks was reared each year in Central Park, and in the New York Zoölogical Park various wild ducks are bred.

The presence of many people whose minds are occupied with other things than wild life tends to make safe not a few wild birds that spend the summers and rear their young in safety close to the city throngs. In the tidewater flats and marshes of Long Island City and of the outskirts of Jersey City, there are still no doubt—as there were a few years since—many places where blackbirds, coots, rails, shore birds, and other species not often seen, breed each year in safety. Duck hawks still rear their young on ledges of the Palisades and it may well enough be that near New York there are other breeding places of large birds.

My boyhood was spent in the country on the banks of the Hudson in Audubon Park. This had been the home of John James Audubon, and was then six or seven miles from the built-up portion of New York City. The only way of reaching it was by train from the Hudson River Railroad Station at Chambers Street, or by a stage which twice a day plied between Saul's Tavern, at 162d Street and Bloomingdale Road, and the corner of 36th Street and Broadway. There were few buildings north of 35th Street, and market gardens, which supplied vegetables to the city, began on the west side of the town near 40th Street, and extended far into the country. Ground for Central Park had just been set aside, but nothing had been done to transform it from a great piece of wild waste land.

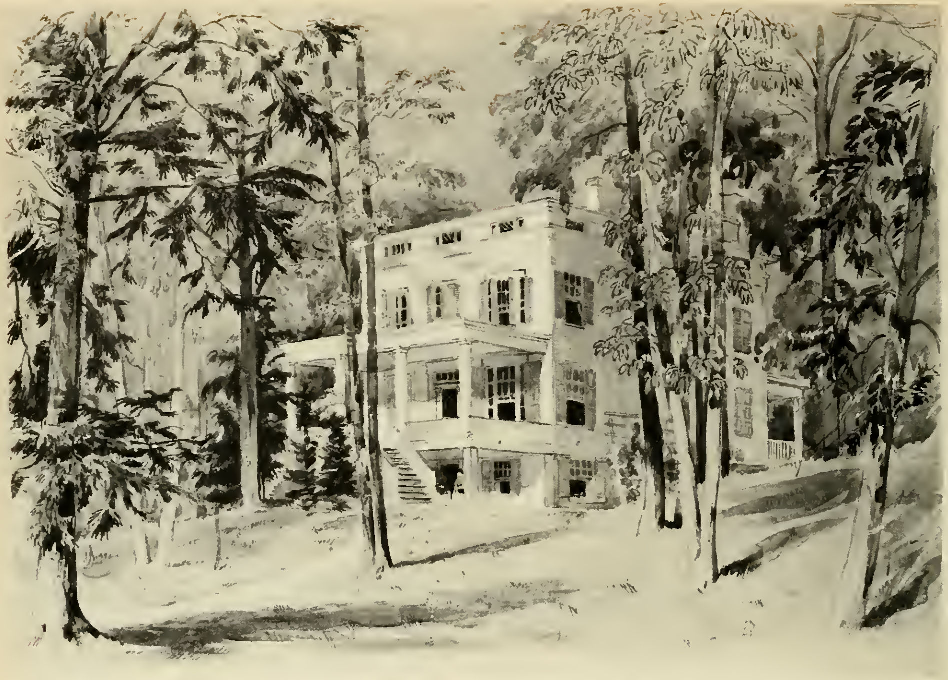
The conditions about Audubon Park were thus those of the country, and no doubt it was for this reason—because of its distance from the city and its freedom from people—that it had been chosen as a residence by the naturalist. In the woods and fields were found many of the birds that occur anywhere in the country of the eastern seacoast. During the migrations, ducks and geese were seen flying up and down the river, or over Manhattan Island; and a list of the birds would not, I suspect, have differed greatly from a bird list made anywhere else along the coast from Greenwich to Hackensack.

A notable feature of the wild life in this once remote region was the music of the birds, and chiefly the song of the wood thrush, great numbers of which nested among the hemlocks and white oaks and the undergrowth that stood there. Morning and evening each singing thrush, perched on the stout branch of giant white oak or hemlock—he seems to prefer that to a twig—poured forth his liquid notes, which, clear as a bell, rang out on the quiet air. Some people used to say that the notes of the thrushes of Audubon Park seemed to possess a clearer, more resonant quality than those of others of their kind, and rather sentimentally connected the sweetness of their song with the associations of the place.

The mammals were not many. There were three species of squirrels, of which the red squirrels were most abundant and the grays least so; while, owing to their nocturnal habits, the flying squirrels were seen only occasionally, although actually they were numerous. Trinity Cemetery was then enclosed by a high board fence, painted gray-blue. The horizontal boards were fastened to rough posts which were hidden by two vertical boards nailed on each side of the post and meeting outside it at an angle. In the high triangular chambers thus formed, there was often much space between the post and the boards, and here the flying squirrels used to make their nests. Some one of the boys at last discovered this habit, and after that most of the neighborhood lads maintained for a time a cage of captive flying squirrels, for the little animals were very abundant.

There were many muskrats on the rather extensive tidewater flats and coves of the Harlem River, and in winter, with Jack Audubon, I often went over to these flats to assist at the shooting of the muskrats.

At that time an arm of the Harlem River ran south through what are now the Polo Grounds, about to 145th



*John James Audubon's house stood between 155th and 156th Streets on the shore of the Hudson River*

Street, but east of this arm was a tongue of land which ran up toward McComb's Dam bridge. This is the present Eighth Avenue. Crossing the tidewater flat—in a general way about where the viaduct at 155th Street now runs, but really somewhat south of it—was a little footbridge, two planks wide, the planks resting on slender poles driven into the mud of the bottom. A footpath ran down the very steep hill near where 155th Street now is, and the little footbridge led from this path across to the solid land to the eastward. In this water there were many muskrats, and after ice had formed over it, they resorted to holes in the ice where we watched for them. They were not often killed, but occasionally one was recovered, and very often we believed we had killed one that had gotten away. Jack Audubon was often permitted by his father to carry his grandfather's gun, and he used it on his shooting excursions.

None of the modern streets or avenues was then open, and there were practically no dwellings along the Harlem River above Harlem Village. The steep, rocky bluff which overlooked the Harlem River, between about 150th Street and the High Bridge, was covered with a growth of tall, hardwood trees, chiefly oaks and chestnuts, and in these trees many crows bred as did also woodpeckers, blue jays, and smaller birds. Little screech owls often occupied the holes in trees abandoned by the golden-winged woodpeckers, and on more than one occasion a small boy thrusting his hand into the hole to feel for woodpecker eggs, found his fingers deeply pricked by the sharp talons of the little owls.

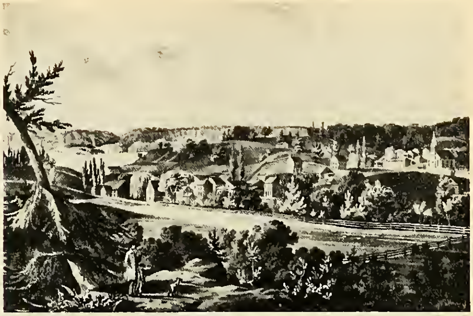
Between 158th Street, which was the northern boundary of Audubon Park, and Fort Washington, a mile to the north of that, was a stretch of woods interrupted in two places only by lanes leading from the main road along the ridge down to private dwellings near the river. In these woods were many rabbits, and I have always believed that on one occasion I started there a ruffed grouse.

At that time, and for many years afterward, there existed near the High Bridge—that is to say, just south of 175th Street, west of Tenth Avenue, and east of the so-called Bloomingdale Road, now perhaps Broadway-Eleventh Avenue—a considerable swamp which possessed a mysterious fascination for the boys of that time and place. Green herons bred there in considerable numbers; that is, we could always find a dozen nests. The birds were tame, for after the novelty of discovery had worn off, the boys seldom disturbed them and they soon became accustomed to the boys. Woodcock bred on the borders of this swamp, and were occasionally seen there and shot at in autumn. South of the swamp, which we called "the green heron woods," was a rather wide extent of pasture land, interrupted by occasional old stone walls and copses of undergrowth, to the point where Tenth Avenue and the present St. Nicholas Avenue cross—about 162d Street. After I had learned how to prepare bird skins, this large triangle was one of my favorite collecting grounds. It was varied in character and was frequented by a multitude of migrating small birds. For many years all this tract has been covered by tall apartment houses.

In this large triangle, which must have been three-quarters of a mile long, I recall but a single building—the old colonial stone structure known as the Cross Keys Tavern. There was a tradition that once Washington had slept there, and when I was a small boy, and perhaps much later, there still swung from a beam projecting out toward the road—west—a large weather-beaten sign on which were painted the two long keys crossing each other which gave the house its name. I cannot recall that it was ever used as a tavern.

During much of the winter the Hudson River was full of ice, on which eagles and crows were constantly seen perched or walking about, feeding no doubt on the refuse and the bodies of animals thrown into the stream farther north. There was a crow roost on a cedar-crowned knoll north—or east—of the Harlem River, but west of the New York, New Haven and Hartford Railroad and south of High Bridge. At daylight each morning the crows flew westward to the Hudson River, and on days when it was foggy or when it was snowing they often flew very low, even among the tree tops. The first crow I ever killed was shot just at dawn from one of the upper windows of the house as it flew over.

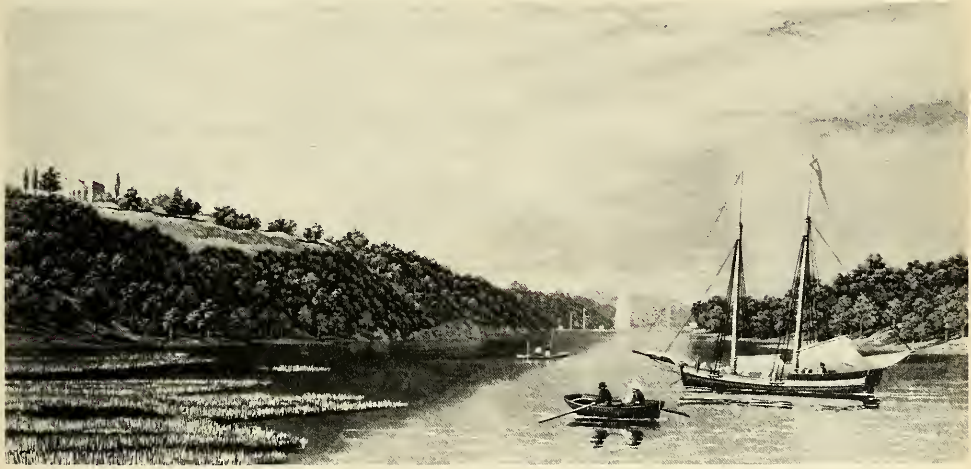
Sometimes the eagles from the river alighted in the large trees not far from the house, and at least on one occasion one of the birds dropped a fish which was picked up by the children.



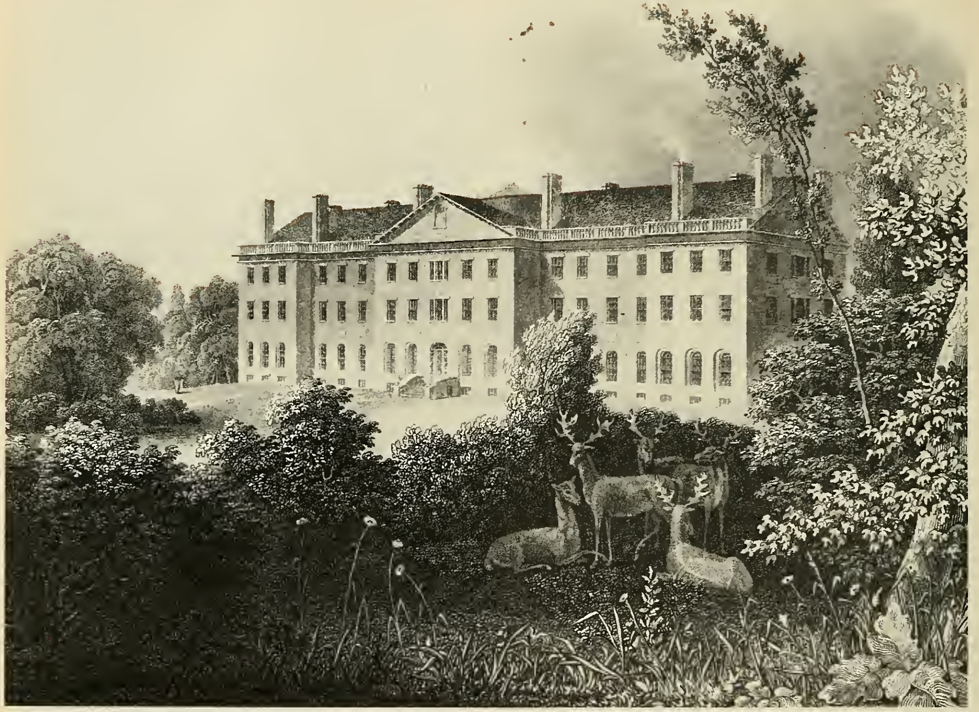
*The village of Manhattanville, drawn here in 1834, lay on the Hudson where the land dips down at 125th Street*

After the small boys of the time were old enough to carry guns, they devoted much of their time at certain seasons of the year to excursions after what they considered game. This game consisted chiefly of small birds, robins, woodpeckers, meadow larks, wild pigeons, and, at rare intervals, a rabbit, or even a duck. In the woods north toward Fort Washington were many dogwood trees, and in autumn when the berries were ripe, birds came here in great numbers to feed on the fruit. We used to sit near such trees and shoot the birds, which in due course were brought home and cooked. As we grew older we extended our wanderings farther afield, and worked our way north to Tubby Hook and to Dyckman's Meadows on the Harlem River where small sandpipers and small herons were often to be had, and at rare intervals a duck was found. Wood ducks and black ducks were the largest game the boys ever secured.

A longer excursion was up to Van Cortlandt Lake—the present Van Cortlandt Park, which we then called "Bronson's." From the lake a stream flowed out toward the Harlem River through a wide marshy meadow, largely overgrown with flags and high grass.



*The "View of the Jet at Harlem River" (ca. 1840) shows the Jumel mansion on the heights at left*



*Bloomingdale Asylum, erected in 1818–20, was north of present-day 116th Street, between Broadway and Amsterdam Avenue*

This, in autumn, was a resort for blackbirds, and here Wilson's snipe were sometimes started, but the small boys never killed them, nor any of the quail which were often seen, but which flew too fast for us.

One spring day I watched for a long time an osprey repairing its nest in a tall tree on a hill northeast of Van Cortlandt Lake. The nest seemed an old one, for it was very large, and the bird, as it swung over the ground in flight, was picking up bits of sod or of dry grass to use on the nest.

I had been to Van Cortlandt Lake long before these days, for when I was a very small boy two or three of the Audubon Park families had driven up to the lake on an all-day picnic. On this occasion my father, who was a great angler, had followed up a brook running into Van Cortlandt Lake and captured there an enormous trout, perhaps the only large fish in the brook. I should not dare to guess how long or how heavy this trout was, but I remember that it was regarded with astonishment and reverence by the other men of the party who had been less fortunate than its captor.

One autumn, soon after my first gun had been given to me, a woodcock made its appearance in our garden—near what would now be the corner of 157th Street and Broadway—and, until cold weather came, gave me a great deal of shooting. After I had learned that the bird was there I went out into the garden each morning before breakfast, found the bird, and shot at it. Later in the day I sometimes found it again and had another shot. I never hit the bird, but had much excitement in its pursuit.

Until as late as 1890 or 1895, quail and woodcock occasionally made their appearance in Audubon Park. The presence of the woodcock was always explainable, but I never was quite clear in my mind as to where quail came from.

Up to the time when that portion of Audubon Park east of Riverside Drive was swallowed up by the city—1909—two or three broods of little screech owls were reared each year in the great trees that grew in the place. From the piazza and the front windows of the house, in summer, the little owls might be seen almost any day dozing in the holes in the trees or on the branches. Now and then the children would find on the lawn a downy young owl that had fallen from a nest, and the work of returning the fledgling to a place of safety was always an exciting task for the children and for the parent birds.

The long-eared owl was occasionally seen on and near the place, and it was reported that the barred owl bred in the woods south of Fort Washington, although I knew nothing more than the report. In winter the snowy owl occasionally appeared, and the saw-whet owl was another winter species.

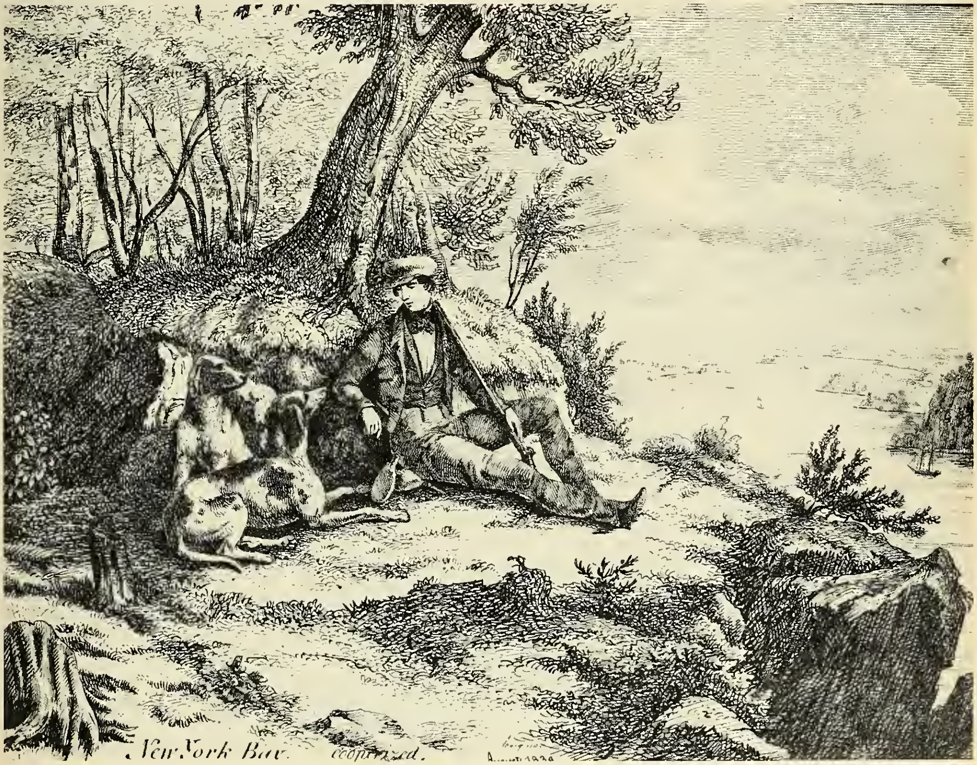
Up to 1909 golden-winged woodpeckers bred in some of the large trees on the place and it is quite possible that today some of these birds may breed in the Trinity Cemetery near by.

Such winter birds as the red and the white-winged crossbills and the snow bunting were occasionally seen, the crossbills as late as 1895–96, when a flock was observed one Sunday hard at work on the cones of a hemlock tree close to the house. A bird seen in winter, but not a winter bird, was a cardinal grosbeak, which made its appearance in February, 1867, on a small dogwood tree close to the house.

Wild passenger pigeons were seen each autumn at this point, and the boys used to have not a little excitement in shooting at them from the top of the house as they flew over north and south. It was discouraging work, for they really flew too fast to be hit, yet occasionally we got one.

New York has been spreading out and exterminating wild life for nearly three centuries. Thirty or forty years before 1860 the Lispenard Meadows afforded good snipe shooting, and in what are now Tompkins Square, Central Park, Broadway from about 46th Street to the North River, and Fifth Avenue at 32d Street, there was good woodcock and rabbit shooting. The growth from small population to great has taken place too often in American cities to cause us much surprise. Our larger wild life has for the most part disappeared, and population has increased so rapidly and territory has been so generally occupied that such changes will be less startling in the future than they are today.

As transportation facilities increased between the southern and the northern portions of Manhattan Island, population spread northward, and with a growing population, conditions became less favorable to the existence of wild life in upper New York. Broadway was opened in this region about 1874, I think, and somewhat later the elevated railway brought a host of people northward. Nevertheless, it was not until after 1900 that the wild birds became notably fewer. But, after the completion of the subway, the march northward of the tall buildings began, and the transformation was rapid.



New York Bay. cooperized.

*To insure accuracy in mounting a horse skeleton, S.H. Chubb took to the air to take photographs of a living animal*

# MOUNTING HORSE SKELETONS TO EXEMPLIFY DIFFERENT GAITS AND ACTIONS

A Glimpse Behind The Scenes At The American Museum

BY A. KATHERINE BERGER

TO convey to the spectator, through the mounted skeleton of a horse, some idea of the nicety of adjustment of every bone, and the positions assumed by it in relation to other bones during pulling, racing, trotting, and walking, is no easy task, and before accurate results are achieved, an amount of study, patience, and care is required little dreamed of by the casual observer.

For more than twenty years Mr. S.H. Chubb, of the department of comparative anatomy in the American Museum, has devoted all his attention to revolutionizing osteological preparation of Museum specimens. In the Museum collections is a nearly completed series of mounted skeletons of the Equidae in which Mr. Chubb is striving to represent with scientific accuracy and in lifelike pose every possible type of horse. There is a giant draft horse and, from practically the same stock, although representing another breed, the Shetland pony. The big horse has been developed through many generations for extreme size, whereas the Shetland pony has been reduced in size by man's selection and breeding. A heavy type of horse is shown in the position assumed when drawing a load. In contrast, there is the remarkable horse "Sysonby," known as one of America's most famous race horses, beautifully mounted to show the running gait characteristic of his kind. The pure-blood graceful Arabian, believed to be descended from an entirely distinct wild species, is represented in the skeleton of "Nimr"; and now the skeleton of "Lee Axworthy," the champion trotting stallion of the world (his record being 1.58¼), is to be added, practically completing the series of domestic horses.

To represent properly the changing curves of the spine of the race horse when he is running his fastest, Mr. Chubb conceived the idea of making photographic studies of a race horse's back in action. Accordingly an arrangement of ropes was prepared and fastened at one end to the roof of the American Museum and at the other to an adjacent tree. A swinging seat suspended from the rope and steadied by guy ropes afforded an unobstructed vantage point for the accommodation of Mr. Chubb and his camera. A race horse was borrowed for the occasion. Certain points of the animal's anatomy, previously determined upon by Mr. Chubb as best marking the constantly changing curves of the spine and the shifting of the muscles in action, were outlined with white patches which would be clearly visible in the photograph. Even the shadow of the horse cast by the sun at right angles was taken into consideration to help portray in profile the position of the horse's feet and body at the moment of exposure. All being ready, Mr. Chubb was hoisted fifty feet above the ground, and the horse was raced back and forth below him while he took photographic studies of the horse's back.

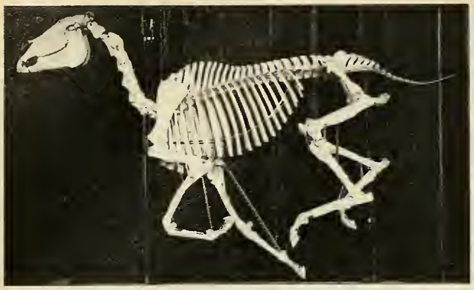
This new and unusual method of photography, also used in the case of the "Lee Axworthy" skeleton, resulted in a series of studies which proved of great value in establishing accuracy of bone adjustment when the skeleton of "Sysonby" was ready for mounting. These studies were supplemented by frequent visits to race courses where many observations were made of horses in action.

There is much to be done from the moment the skeleton is dissected to the time the bones are finally mounted. Sometimes these tasks are very time-consuming; eleven months were required to prepare the skeleton of "Sysonby" for exhibition.

The writer had an opportunity to witness a part of the preparation of the skeleton of the trotter "Lee Axworthy," listening the while as Mr. Chubb explained the process in progress at the time. Mr. Chubb was seated at a long table busily engaged in scraping from the sternum of the skeleton fragments of flesh and soft tissue that still adhered to the bone. Near him on the floor were several jars containing water in which were immersed various parts of the skeleton.

"When sufficiently decomposed the ligaments and tissues are removed and all that remains after dissecting is scraped away as clean as possible," he said. "If the surface of the bone dries too rapidly, it contracts and splits, while the inside is still wet. Slow drying is preferable and will prevent such injury by permitting the entire substance to dry evenly. The next step is to free the bones completely from all grease, that they may become spotlessly clean and pure in color before they are articulated."

Immersing the bones in benzine and exposing them while in this medium to daylight and sunshine for a number of weeks will accomplish the desired result most successfully. The benzine must be changed two, three, or possibly four times during this period, because it becomes saturated with the grease.

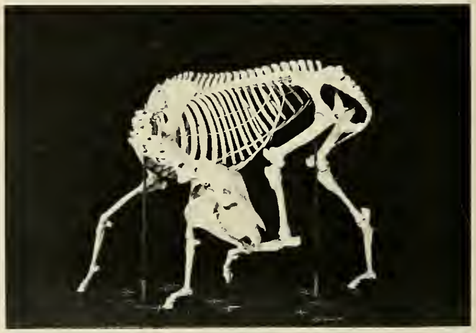


*The skeleton of the racehorse Sysonby, in position for permanent mounting*

"After the benzine process," said Mr. Chubb, "the bones are ready for mounting. First, I get a steel rod as nearly as possible fitting the opening and extending the length of the neural canal of the spinal column. This rod I must shape to the curve of the spine. Then the vertebrae are hung tentatively in place. Next, I gradually study the bones of the legs, which I fasten together temporarily so that any change can easily be made in the angle of the joints. The legs are suspended by looped cords passed over the heads of small screws, which are inserted in the bones at various points. The other ends of these cords are passed several times over horizontal rods above. To these free ends are attached small weights sufficiently heavy to prevent slipping, thus affording easy and convenient adjustment. Now comes the delicate task of getting the bones into the position which seems to suggest the action I have in mind, and seems to do it in a perfectly alive and satisfactory way. Getting the ribs in position is a long operation. I take a very small piece of pliable steel rod and fasten to it the several ribs, each by means of a rubber band. Then I study the little articulations. Finally, when they are all satisfactorily placed, I devise a permanent brace to fit the ribs and hold them enduringly in place. Every step, meanwhile, is checked up and corroborated by constant comparison with a great number of photographs.

"As I get the adjustment nearer and nearer perfection, I see errors in this part or that which were not obvious when the bones as a whole were out of position. It is simply a process of eliminating the errors until the whole becomes perfect. When all is right, I drill small holes where the bones come in contact with each other, and into these holes drive steel wires just tight enough to hold firmly but not tight enough to break the bone. Where there are many little bones, wires are driven in from opposite directions to bind all together as firmly as possible. These wires are driven down just a little below the surface of the bone, and the small holes which result from this operation are filled up later with plaster."

In studying the trotting modifications found in the skeleton of "Lee Axworthy," Mr. Chubb remarked that these might possibly be found in a race horse, but they were not evident in the skeleton of the race horse "Sysonby." On the front pastern (but not in the hind) of the skeleton of "Lee Axworthy" was a slight depression in the bone due to extreme movement of the pastern joint in the trotting action. Said Mr. Chubb, "I can imagine that this might become adaptive and prove of great advantage in that particular action, but we cannot say that it has gone far enough at present to be of great consequence."



*This mounted skeleton of a donkey relieving an itch was Chubb's last work*

---

The skeletons of a horse and a man, painstakingly assembled to depict the man in the act of seizing the rearing animal's bridle, constitute the best-known example of Samuel Harmsted Chubb's art. The work serves today in graphic form as a symbol of the American Museum of Natural History. "It shows the superiority of intelligence over size," Chubb said of what was one of his favorite pieces.

Born in 1863, Chubb, the son of a doctor, became interested in skeletons as a young boy and would drag home specimens of dead animals for examination. His formal education ended after grade school, and at the age of sixteen, Chubb went to New York City, where he found work as a machinist. His first connection with the Museum came in 1892, when he showed samples of his osteological work to Henry Fairfield Osborn, who purchased the skeleton of a cat for $40. Several years later, Chubb left his job as a machinist to become a free-lance osteologist, and in 1901, he became formally associated with the Museum. Throughout his career, his training as a machinist enabled him to prepare the steel bases and mountings needed for the lifelike display of bones.

Chubb eventually became associate curator emeritus of comparative anatomy and remained active in his work until his death in 1949. In his nearly fifty years on the staff of the Museum, he worked on countless specimens, paying careful attention to the tiny vestigial bones that are of special interest to students of evolution. Only a fraction of these materials were ever put on display, and today, even the cases containing the skeleton of the racehorse Sysonby and other major pieces have been moved to storage. There are no plans to place these skeletons back on public view, but they will be distributed to the Museum's various departments and to other institutions to make them more available for research.

# SAMOAN CHILDREN AT WORK AND PLAY

Childhood and Youth. A Tropical and Idyllic Land to Which the Modern Psychological Problems of Civilized Youth Have Failed to Penetrate

BY MARGARET MEAD

WHEN anthropologists make trips to the far corners of the earth and search out the primitive peoples who live there, they add to our knowledge of the different ways of life under which human existence is possible, of the different kinds of demands which human beings can meet bravely and well.

It was to add to our store of this kind of information that I went to Taū, a little island in American Samoa, and spent nine months living among the few hundred South Sea Islanders who inhabit it. I went there to make a study of Samoan children and Samoan girlhood, to find out if the pains and pangs of growing up were as difficult in Samoa as in America.

This was no problem which could be solved in a flying trip. I could not just walk into the round, unwalled houses, with their high thatched roofs and pebbly floors, sit down on the mat which is always spread for strangers, and say to the guest-house mother who sat nursing one baby while a little older child tangled her half-finished mat, "Well, now, tell me, what are your children's names? How old are they? And Flower is the oldest? Does she take her responsibility seriously? Is she good and obedient? Is she bossy with the other children? Was she jealous when the new baby came?"—and then pass on to the next mother and ask her the same kind of questions, putting the answers all down on cards, to be counted and written up after I got back. If that mother, in her soft Polynesian language in which her children and I made the same mistakes, had answered my questions directly, I should not have understood her answers. For they would have run something like this:

"Names—well, the baby's name is Pandanus Nut, that's what we call it, or just Nut for short. But its name from its father's father's family is 'The One that Does Not Move,' and only yesterday my younger brother gave it his name of 'Lighted House,' so perhaps we will call it that now. And how old is he? Well, he was born after the second Palolo Fish Feast, and before my young cousin, Hibiscus, had her baby girl. He can't walk yet. The next one to the baby is called Bonito Fish. He is a boy. I don't know how old he is. And Flower, she is a girl, is the oldest of my children who are at home. There is that one, a boy, his name is White Stone, who lives with my mother, and the girl, her name is Jelly-fish, who lives with my first husband's sister in the next village. No, my first husband isn't dead! He's married to the sister of that woman with the banana leaf over her head, who is going down to the sea for water. I don't know what you mean by responsibility. Do you mean she has got common sense in her head enough to know that she mustn't play with her brother nor touch any of his things? She listens easily, not like my brother's children, who listen with difficulty to my brother's commands. Is she bossy? Of course she is bossy to all those in the family who are younger than she is, and listens to the wishes of all those who are older. And which new baby do you mean? My sister's baby, or my younger sister's baby, or my brother's wife's baby? But of course she was glad when all the babies were born."

Only after I had learned to speak the language well, and had spent long mornings sitting gossiping over a coconut or a plate of bananas, after I had learned to plait mats and blinds and helped the harassed homeless

*Samoan children in the shade of coconut palms*

*The heir apparent of an important chief*

people rebuild the village after a devastating hurricane, and had spent even more hours with the little girls themselves, searching for shells, weaving flower necklaces, coaxing land crabs with a low, sweet chant, or swimming in a hole in the reef, did I come to know enough about the Samoan way of life so that I could have understood those answers.

Samoan children's names change often, at the whim of any relative. As soon as they are old enough, they are allowed to choose new ones for themselves upon any occasion. And similarly they choose their own homes, living now with a grandmother, now with an uncle. Families are not made up of father and mother and children, but of some fifteen or twenty relatives among whom there is no oldest child, because a young aunt or cousin will be nearly of an age, among whom the same child is never "youngest" for long. And in these great households the mothers take little care of their children after the babies learn to crawl. The nurses are not young girls but toddling five-year-olds, who trundle about upon their hips babies that are too heavy to be lifted into their arms. Samoan children are not carefully disciplined and supervised until they are five or six, and then, properly trained, given some freedom. They are spoiled and pampered by their baby nurses until they are five, and then, if they are girls, they are turned into nurses themselves; if they are boys, they are turned over to the rough but thorough discipline of older boys. At ten years of age they are sturdy, well-behaved youngsters, although their bringing-up seems so strange to us.

Samoan parents do not hide anything from their children; they tell them no fairy tales about the birth of babies nor do they pack them off to a relative until after a funeral. They believe quite literally that children should be seen but not heard, should be present but make no comments, should learn the important facts of life from careful observation, not from random, groping experimentation. And the children grow up, acquainted with the rhythm of life and death, accepting life as simply and unrebelliously as do their parents.

Nor do Samoan parents think children should not work. The tiniest little staggerer has tasks to perform—to carry water, to borrow fire brands, to fetch leaves to stuff the pig. And these slighter tasks are laid aside for harder ones as soon as the child becomes strong enough or skilled enough. At the preparation for a feast to celebrate a visiting chief, a marriage, or a new canoe, the little children feel very serious and important, and go scurrying about the village, muttering, "There are very great complications in my household." Learning to run errands tactfully is one of the first lessons of childhood, and a child of nine will be trusted to take a valuable piece of bark cloth to barter for a pig.

This attitude toward children as little adults although lacking in experience and sometimes sadly devoid of common sense, makes for a different kind of play also. Samoan children have no dolls, no play houses, no tea sets, no toy boats. For dolls they have real babies; at six they are expected to sweep up the real house and pick all the scraps off the floor. Little boys anxious to become boatmen paddle about in real canoes within the safety of the lagoon. Embryonic eel fishermen hold the bait for their big brothers, but never play-act fishing in a pail, or catch a leaf and pretend it is an eel. Yet they have their games, playing at ball with square light balls made of pandanus, stringing necklaces of flowers, playing round games to merry songs of their own improvising in the dusk. And in all these they but imitate their elders, who follow a morning of work and an afternoon of sleep with an evening of dance and song.

Strangest of all to us is the Samoan opinion of precocious children. To be brighter than your age, to stand out conspicuously above other children, this is the sin for which a child is roundly scolded and sometimes whipped. So it is that the happiest children are those who like to be children, who put off responsibility, who do what is asked of them without aspiring to more grown-up tasks, those who answer in lazy content, "I am but young."

---

"Samoan Children at Work and Play," Margaret Mead's first article for *Natural History*, was based on her earliest field research. In the preface to the 1973 edition of her book *Coming of Age in Samoa*, she recalled, "I did not know then, could not know then, how extraordinarily persistent Samoan culture would prove, and how fifty years later the grace that I had attempted to record as something that was surely going to vanish would still be there." Curator emeritus of anthropology at the American Museum of Natural History, Margaret Mead died in New York City on November 15, 1978.

# CAN WE SAVE THE MAMMALS?

By

HENRY FAIRFIELD OSBORN AND HAROLD ELMER ANTHONY

The American Museum of Natural History is working hand in hand with the New York Zoölogical Society, with the Boone and Crockett Club, with the American Game Protective Association, with the American Bison Society, and the National Association of Audubon Societies, with the United States Biological Survey of Washington, with the National Parks Service of the United States Department of the Interior, with the American Society of Mammalogists, and with officers of the British, of the Indian, of the Australian, and of the British Colonial and Insular governments, to retard the inevitable CLOSE OF THE AGE OF MAMMALS. This title is not the cry of the alarmist; it is the expression of an actual and most melancholy fact, namely, that the glorious AGE OF MAMMALS is closing, that man will soon be alone amid the wreck of creation; that many of the races of man himself are passing under the inexorable law of extinction. The title "CAN WE SAVE THE MAMMALS?" is designed to strike a note of hope as to what yet may be accomplished toward salvaging for the future the little that remains of the wreck of the past.

FORTY years ago the birds of the world were in great danger of extinction, partly because of the ruthlessness of the man with the gun whom we will not designate a sportsman; partly because of the frivolous demands of the equally ruthless woman of fashion. As a glorious reward to the friends of the Audubon Societies in America and of the Plumage Bill Group and similar societies in Great Britain, the birds have been saved in English-speaking countries. Irresponsible destruction of game birds has been checked all over the North American continent and birds of all kinds are now multiplying. The destruction of birds of beauty and of song for the relentless purposes of fashion has been stopped so far as North America is concerned, and has recently been arrested all over the British Empire; it remains to check and stop it in the Latin countries. Not yet can it be said, however, that the birds of the world have been saved, because destruction of the superb pheasant family (Phasianidae) of Eastern Asia and of the still more brilliant birds of paradise (Paradiseidae) of New Guinea and adjacent islands is still proceeding with alarming rapidity.

The saving of the birds renders us hopeful that certain of the finest kinds of mammals, including those which are nearing extinction from natural causes, as well as many of the fur bearers that have been reduced in numbers through persistent persecution, can still be saved by three great movements along lines similar to those which have resulted in the preservation of the birds and of certain forests.

*First,* we may point out the alarming rate at which the mammals are now being slaughtered for commer-

*Siberian furs worth $100,000 on the wharf at Nome, Alaska, 1906*

Bettmann Archive

cial purposes and demonstrate that such devastating measures are ill-advised in that they are defeating their own ends. By pointing out the inevitable consequences of the rapid destruction of trees, conservationists were able to save some of the historic forests of Europe and of America. Those championing the right of survival of our game animals may in like manner refer to the fact that the unchecked destruction of any natural species, whether it be a *tree,* a *bird,* or a *mammal,* may mean an immediate monetary gain to a few individuals, but must mean ultimate monetary loss, not to mention *moral* and *spiritual* loss, to the entire community, while posterity is thereby robbed for all time of what should rightly be part of its heritage.

The *second* measure in this great conservation movement is again similar in character, whether it concerns trees, birds, or mammals: it is designed to prove that the final destruction of a species is against the general welfare, that it is unnecessary because stimulated by entirely *artificial* and not by real human needs. We cannot deny fur clothing to the Eskimo, a fur coat to the northern woodsman, the reasonable use of furs in civilized communities for dress and for ornament, any more than we can deny the reasonable use of trees for economic purposes, or of birds as a natural source of food supply. It is not the reasonable use of mammals which is bringing the great AGE OF MAMMALS to a close; it is the unnatural uses created by entirely artificial means, such as the wearing of furs purely as a means of display of wealth and for the purpose of gaining social position or standing.

Our *third,* and what may ultimately prove to be our most effective, measure in trying to save the mammals is that which has been applied to such advantage in the case of the birds, namely, creation among our school children of the sentiment of conservation, of the love of nature, of the appreciation of the wonder and beauty of mammalian life, of the realization of the great efforts which nature has put forth to produce the mammal kingdom, and of the enormous periods of time that have been required for its evolution; the sentiment, moreover, that mammals are the friends of man, that they are prototypes of our strength as well as our weakness, that they are among our best companions, that even some of the wildest of animals will become tame and companionable as soon as the gun of the market hunter and that of the sportsman are silenced.

These three watchwords of the mammal conservation movement are like the little flags known as guidons which direct lines of cavalry both in army maneuvers and in battle. Conservation is, in fact, partly a matter of skillful maneuvering following a long period of preliminary public education; it is also partly a matter of downright warfare. Some veterans, like the dean of American conservationists, Dr. W. T. Hornaday, always sound the battle cry; others, like the late lamented C. Gordon Hewitt, leader of the conservation forces in Canada, try to advance by the gentler methods of conciliation and of education. To save the mammals it is certainly necessary to marshal all our forces, both militant and persuasive, and to use all or any of these methods.

To enlist the coöperation of the readers of NATURAL HISTORY, let us present as our first line of attack some of the facts of the present period of slaughter which lead us to believe that unless there is a drastic change of action the AGE OF MAMMALS is coming to a close.

*Showroom of Rosensweig and Schwartz, furriers, 1920s*

Bettmann Archive

Nothing in the history of creation has paralleled the ravages of the fur and hide trade, which, with the bone fertilizer trade, now threatens the entire vertebrate kingdom. Furs are no longer worn primarily for protection in cold weather. Furs are now a fashion, just as feathers were forty years ago. The trade has passed almost entirely into the hands of people of Oriental and Asiatic origin. Millions of dollars are spent annually in advertising. Furs are worn in midsummer purely for personal adornment, or to make a display of wealth and luxury.

Some realization of the destruction now going on among the mammals is afforded by a glance at the statistics of our fur trade. After consulting a great number of fur-trade journals and reports, Mr. Anthony has compiled figures for the years 1919, 1920, and 1921, showing the large number of skins sold all over the United States at the fur auctions. The best of these journals is the *Fur Trade Review,* a large monthly publication given over to everything of interest to the fur dealer. In the *Fur Trade Review* one can find a list of all offerings at the different fur auctions, and it may be assumed that these figures are sufficiently authentic to be used in this article. In interpreting data of this nature, there are several features to be kept in mind. It is possible that the records of skins sold during any one year will not be a true record of the actual killing for the period in question, inasmuch as, during a time of high prices, skins may be brought out of storage to be marketed under favorable conditions. A large number of skins sold during

a certain year may, therefore, have been collected over a period of several years. However, as we have had a few "boom" years, it is quite likely that all of such stored skins were brought out sometime ago and disposed of, so that the more recent figures probably indicate animals killed within a year of their sale. Furthermore, lots of skins may be sold at a spring auction and shipped to another part of the country to be resold in the fall, thus giving a duplication of numbers. However, omission of the winter sales of 1921 from this list more than offsets any duplication that may have occurred.

The discounted total of all skins sold for the three years in question reaches the alarmingly large figure of 107,689,927 skins. Moreover, this figure indicates only the slaughter of the animals which reached the market as skins. To show properly the actual slaughter that is taking place, one must allow for animals that were killed but not sent to the market because their skins were unprime, also for a considerable percentage of wounded animals which, although they escaped the hunter, were killed nevertheless, through his agency. A glance at some of the more noteworthy species sought by the fur trade that are indicated in the preceding table will show something of the scope and demands of this industry. Altogether the fur trade utilizes, at the very least, about one hundred twenty-five species, the exact number being difficult to determine because of the employment of trade names, which mean nothing to the zoölogist. Mr. Anthony has included in the table only thirty-two of the more important species out of the one hundred twenty-five species which are being destroyed.

A glance at the figures showing the number of skins of beaver (*Castor canadensis*) sold demonstrates what proper protection of a fur-bearing species may accomplish. Formerly trapped all over the American continent, beaver were brought almost to the verge of extermination, but for many years they have been protected and allowed to increase unmolested. As a result, during the period of the past three years, about 420,000 skins have come to the market.

The table indicates how relentless has been the pursuit of the muskrat (*Fiber zibethicus*), an animal which at one time brought such a low price at the sales that it was scarcely worth while to trap it; when muskrat fur came into fashion under the trade name of "Hudson seal," and the public demanded it, a systematic campaign of trapping began which brought muskrat skins to the market by the millions and now seriously threatens the very existence of this species. Squirrel (*Sciurus*) skins, most of which, we believe, have come from the Old World, make up a huge total of more than 14,000,000, and this is another example of a skin, formerly valued very slightly, that has come into prominence because of the demands of fashion. Skins of the insectivorous moles (*Talpa*) reach even a larger aggregate. The skin of the mole is so small that only since the passion for furs has become extreme has there been any incentive for men to molest this animal. Most of the skins disposed of at the sales listed on the table must have come from the Old World, and the mole, as anyone knows who has tried to trap it, is an exceedingly difficult animal to capture. More than 23,000,000 of these little animals were sacrificed to the insatiable demands of the fur trade. The mole, it may be claimed, is a small, insignificant species, and here and there among the list of fur bearers are other animals for which no economic value may be urged, but the presentation of this subject is intended to show the great destruction of mammal life, irrespective of species, and the possible desirability of exterminating any particular animal does not enter into the discussion.

The mink (*Putorius vison*), which was one of the first fur-bearers to be trapped in this country and which has remained a favorite for the past century, is an animal that apparently nowhere survives in very great numbers. However, since its skin has brought such a good price at auctions, our country has been combed over for mink, and the annual average yield of the last three years has risen to more than 500,000 skins. This is a very serious, if not fatal, tax upon the ability of the animal to maintain itself. The winter fur of the ermine (*Putorius arcticus*) has been worn from time immemorial and has been the fur of royalty. Today its use is much more general, witness the fact that no less than 4,400,000 skins of these little animals have come to the market during the three-year period. Before the recent craze for furs had begun, the skunk (*Mephitis*) enjoyed the immunity which nature intended him to have, and his skin brought such a low figure at the auctions that it scarcely paid anyone to run the risk of removing it. Now skunk fur commands such a high price that the trappers have covered all the American forests and plains area and more than 6,000,000 skins of this animal were disposed of at the auctions held from 1919 to 1921.

The raccoon (*Procyon*) is another animal the fur of which had but little value in early years; but to show how its status has changed, it will be necessary only to point out the total sales for the three year period, amounting to 1,700,000 skins. One of the furs most widely sold today was formerly worth but a few cents—we refer to the American or Virginia opossum (*Didelphys virginiana*). In those days there were few individuals other than boys who would give their time to skinning it, but since it has come into fashion, a vast number of market hunters have obtained the more than 9,700,000 skins subsequently placed on sale.

State Historical Society of Wisconsin

*Three trappers from the vicinity of Fall River, Wisconsin, pose with the skins of more than 500 muskrats, ca. 1910*

The average man has been led to suppose that wolves of the forests and plains have become almost extinct over most of the country. In the figures given for the wolf (*Canis lupus*), there are lumped together a great many species of coyotes and wolves, but, even so, the very large total of more than 1,000,000 skins is very significant of the great campaign that is being carried on against this animal, and at this rate it will not be very long before the wolf is extinct indeed. The red fox (*Vulpes fulvus*) has been such a prime favorite that great numbers of skins of this animal have come to the fur sales, and we understand that in some regions of the north the fox is virtually on the brink of extermination. More than 1,200,000 skins taken during the three-year period evidence a rate of destruction far greater than that which an animal like the fox can survive. On the other hand, the rarer foxes, the silver and the black, have been protected and reared in captivity, and we have learned upon good authority that most of the skins sold are those of ranch-reared animals. The fact that it was possible during the three-year period to place on the market the skins of more than 26,000 ranch-reared foxes furnishes a clew as to the proper methods for supplying the fur market.

The sea otter (*Latax lutris*), which furnishes the most beautiful of all furs, was represented on the fur counters by only seventy-six pelts—a sad commentary on the disappearance of this animal. Inasmuch as the sea otter is protected over most of its known range, some of the skins were doubtless taken illegally and unless some radical change for the better takes place, it will no longer be obtainable by the fur dealers. When the killing of the Alaskan fur seal (*Callorhinus alascanus*) had reached such serious proportions that the government found it necessary to intervene, and treaties were entered into establishing the right of this country to protect this animal, the northern herds were placed under supervision and the annual killing controlled by law. This regulation has worked out most satisfactorily, and a glance at the figures shows that over the three-year period more than 85,000 skins were sold—a very satisfactory total when one considers the high price commanded by the individual skin.

The figures just cited give a little insight into what

Bettmann Archive

*Selling silver fox skins*

the fur trade is doing toward bringing about the close of the Age of Mammals. In a few years some of the mammals now sought by the trappers will be killed off to a point where they will not repay trapping, the numbers taken being insufficient to justify the expenditure of time and effort. Meanwhile, America has become the center of the fur trade. Before the war London was the world's fur market, but it now appears that the control has passed to the United States, and the great market of the present day is here.

The figures given out by the Fur Dressers and the Fur Dyers Association show that in New York City alone more than 80,000,000 skins were dressed and more than 97,000,000 were dyed by the members of this association during 1918, 1919, and 1920. Thus it would appear that the life of this industry throbs in our own country, and if any proscription is to be written, such as may serve to prolong the trade itself, the initiative should be taken by America. The more intelligent fur dealers realize that the wild animals are an asset to their industry, and judging by the editorials of the different journals, and the articles that appear, we believe that the majority of such fur dealers, if the matter were put to a vote, would encourage more humane methods of trapping and a more extended control over the wild animal supply. It would suit their own purposes better if animals could be taken only during that part of the winter when the furs are in their prime; the restriction of the hunting period to such a time of the year would be an important step toward the conservation of fur bearers. But as matters now stand, when fur prices begin to mount to such figures that a few skins represent many dollars, then in the out-of-way places where laws have but little significance at any season of the year, men go out and kill every fur bearer that they come upon, and run out their traps for whatever they may catch. Therefore, we believe that if some more intelligent and humane methods of checking this appalling slaughter are not soon inaugurated, the fur craze will have been the means not only of closing the Age of Mammals but of terminating a great industry.

From the standpoint of the naturalist, the Age of Mammals has long since closed as compared with the close of the Age of Reptiles, which occurred more than three million years ago. Extermination of the large mammals has been going on for a century; extermination of the small mammals has been extremely rapid in the last two decades. In North America alone mammals, broadly speaking, have disappeared within our life time. The present rate of destruction throughout the world from various causes is probably not less than fifty million a year, of which thirty million represents the demands of the fur trade. The bison is extinct in the United States except for the animals preserved in parks. Through the splendid efforts of the American Bison Society this noble quadruped is rapidly multiplying.

In Canada the wood bison is still holding its own and is, perhaps, slowly increasing. The elk, or wapiti, has disappeared from the greater part of its old range and is now found in its wild condition in only a few of our western states. On the danger line of actual extinction is our beautiful pronghorn antelope, the existence of which is seriously threatened, especially because of the great difficulty in supplying it with its natural conditions of life. Our other two large mammals, the Florida manatee, a wonderful "living fossil," survives in a restricted area and in limited numbers; the splendid elephant seal of the Pacific has been completely killed off except for a small colony in Guadeloupe Island. The sea otter has been very nearly exterminated along the American coasts. The American beaver is extinct over most of its ancient range but has increased in an astonishing manner in the areas where it is protected. Among the great mammals of the sea the California gray whale is nearly extinct. The right whale is in danger of extermination, and the disappearance of the bowhead whale is also threatened. The American Museum has thus far failed in its efforts to secure examples of this splendid species of whale before it disappears.

In many parts of the world, in Australia, in northern and southern Asia, and in North and South America, American Museum explorers are charged with the mission of securing single specimens of these fast-vanishing remnants of the AGE OF MAMMALS before it is too late. Many of the specimens which the Third Asiatic Expedition has secured will be among the last of their kind to find their way to the great museums of the world, because Mr. Roy Chapman Andrews, the leader of the expedition, has observed that their numbers are limited and that they are in near danger of extinction.

---

In 1972, 1.7 million items manufactured from wildlife were imported into the United States. This figure had soared to 164.6 million by 1977, for a tremendous increase of 9,582 percent.

In 1973, 2,800 game trophies were imported into this country. Four years later, the figure was 19,300, an increase of 589 percent. Skin and hide imports rose from 910,000 to 1.15 million during this same period, up 26 percent.

In 1974, 161.3 million live animals were imported. In 1977, the number was 164.8 million.

According to Nicole Duplaix, director of Trade Records Analysis of Fauna and Flora, an office of the World Wildlife Fund-U.S., there is only one inspector from the U.S. Fish and Wildlife Service available at any one time at the Miami airport, a major port of entry. Incoming shipments of wildlife and animal products number hundreds per day.

BYRD ANTARCTIC EXPEDITION

# OVER THE SOUTH POLE BY AIR

Some Phases of the Polar Region Survey of 1928–30 Achieved with
All the Practicable Appurtenances of Modern Science

By REAR ADMIRAL RICHARD E. BYRD

As Told to Albert D. Barker

IN two hundred years of Antarctic exploration, the questions that have been raised about this great expanse of land buried beneath the earth's largest remnant of the Ice Age are as many as the blocks of ice in the vast, floating pack that encircles it. To seek solution of a few of these problems and to do the seeking with all the practicable appurtenances of modern science was the chief aim of the Byrd Antarctic Expedition, though, as was inevitable, the first flight by airplane ever made over the South Pole was bound to receive the public's principal notice.

Obviously I cannot in brief space chronicle the many events of an expedition that required three years of preparation; that left New York in August, 1928, and did not return until June, 1930; that was moved about 20,000 miles in two ships; that built its own village upon the ice and lived in it, usually buried by snow, 2300 miles from the nearest human dwelling; that for nearly fourteen months thrived in an almost lifeless land, in temperatures averaging about 16 degrees above zero in the warmest month and about 42 below in the coldest, did its work and returned without mishap.

To tell a fraction of this story is impossible, but I may well touch upon some of the ways in which this big undertaking differed from expeditions of the past and pointed to the modern methods that will greatly hasten the future scientific surveying of Antarctica.

Perhaps first comes to mind the extensive use made of the airplane by this expedition, which landed three on the ice barrier and flew them with entire success both before and after the winter night and in temperatures that were always low and often severe. The significance of the airplane in exploration like that done from Little America as a base is two-fold: It covers distance in minutes and hours instead of days and months, and it broadens the horizon five-fold. Hardly less important is a third related consideration. Using an aërial camera, the explorer now for the first time is able to bring back indisputable evidence of what is seen over wide areas.

There is no better illustration of these points than the South Pole flight. Amundsen, in his heroic "dash" to the Pole by dog team and afoot, required nearly 98 days to go and come. The "Floyd Bennett" took us there and back, with a minimum of physical hardship, in 19 hours. While Amundsen at the best was observing a terrain visible on either side for a distance of 8 miles only, our horizon averaged more than 50 miles. On level snow he commanded a panoramic view of 75 square miles; at 10,000 feet of altitude, we looked down on a world of more than 50,000 square miles, and at much lesser altitudes still immensely exceeded his range of vision.

Further, as this expanse of milky snow and ice and looming mountains unfolded, Capt. Ashley C. McKinley, third in command of the expedition and its aërial surveyor, was taking—instead of mental or pencil notes—an overlapping photographic record. The area covered in that one flight of less than a day's duration was about 150,000 square miles, the new and less known portions of which almost literally were brought back to New York on photographic negatives. In the various flights 150,000 square miles were surveyed by camera, an area which, if you are curious to visualize it, almost equals that of West Virginia, Ohio, Indiana, and Illinois combined.

The expedition made in all 23 flights and traveled by airplane about 7085 miles. Through use of this modern aid, the airplane, it covered an area of 500,000 square miles, of which 250,000 had no overlaps and 200,000 square miles, it is estimated, never before had been seen by man.

At the South Pole we were some 800 miles south of Little America, which, as I have said, was 2300 miles from any dwelling. An airline between our plane and New York would have measured nearly 10,000 miles. Below was nothing but a level plateau of dazzling snow—which as the camera records it, looks like a sheet of pebbled white paper. So we might, in all truth, have considered ourselves to be stark alone at the "end of the earth." Yet, in point of fact, my message that we were in the vicinity of the South Pole was almost instantly received at Little America, and quickly relayed to *The New York Times.*

News that under former methods of polar exploration might have reached "the outside" in a year or more, thus became the property of the civilized world within a few hours. With the radio, "the outside" has been moved right into camp and into the kit of every airplane and sledge party. No exploring or survey party left Little America on an extensive trip without the means of communicating with the base by radio. Indeed, on one flight an operator, listening in at the *Times* station in New York, caught the exchange of messages between plane and camp.

Shortly after we celebrated Christmas, 1928, by reaching the barrier ice in the Bay of Whales from our outside base at Dunedin, New Zealand, we had selected a permanent camp site on this great ice shelf a few miles inland, and hauled by dog sledge the 650 tons of supplies and material brought by the "City of New York" and the "Eleanor Bolling." The planes were one of our first concerns; as was the radio. Soon we had erected the three metal 60-foot towers and set up the mechanism of the Adolph S. Ochs station. Communication established, not a day elapsed whose events were not reported to the public. For the first time, a remote expedition was regularly breakfast-table news; for the first time, the members of such an expedition listened to radio broadcasts from a big city station and received word from their families; for the first time, business could be transacted between such an expedition and its headquarters 9000 miles away in an air line.

The radio, however, was not limited in its functions on this expedition to the practical uses that proved so immediately valuable. Many phases of radio reception and sending under the unusual conditions that were inherent in the location were studied and recorded—for instance, the varying phases of the local heaviside layer throughout the seasons.

*Byrd Expedition flagship,* City of New York, *returns to New York Bay*

But radio and airplane were only two of an array of modern aids to scientific investigation contained in the expedition's equipment, which was unusually complete. All the instruments requisite for geological, weather, and other studies were at hand and put to thorough use. The data records are being worked up and studied—a labor which will require months more.

Reporting officially by radio in June, 1929, to the Secretary of the Navy on our discovery of the Rockefeller Range of mountains, I said, "Aviation has discovered a new land, surveyed it and landed on it for scientific investigation." Prof. Laurence M. Gould, second in command of the expedition, its geologist and a leader in various scientific endeavors, went by plane to the base of this range, made extensive ground surveys with which to check the air survey, and with his party climbed the mountains to study the rock formations and take specimens from several of the 40 peaks and ridges, the highest 2075 feet.

Next season, Doctor Gould, using sledge teams—and let me say that the sledge dog, despite advances in science, is still indispensable in the Antarctic—laid a line of food and supply bases to the foot of the Queen Maude Range, and made a thorough geological study of the mountains and other formations at that point. Doctor Gould on this trip found sandstone and carbonaceous material, though his earlier findings had been mainly confined to granite.

For nine months the expedition made continuous photographic records of the magnetic elements, supplemented by absolute measurements with instruments. This work, done under severe conditions in snow and canvas houses where the temperature averaged 20 degrees below zero, showed greatly disturbed magnetic conditions. The observations covered the maximum of a sun spot cycle of considerable importance. A very complete part of the magnetic study was the record—as to types, intensity, direction, and color movement—kept of the auroras, which occurred on 90 per cent of clear nights.

As the Antarctic is one of the greatest birthplaces of "weather," we had the equipment of a first order Government weather observation station in charge of William C. Haines, meteorologist, but carried our studies also into channels not usually entered. Hourly, day and night, we took a systematic record of barometric pressure, temperature, cloudiness and precipitation, wind direction and velocity, humidity, visibility, and other phenomena. With kites and pilot balloons we made investigations of the upper air, reaching in these soundings altitudes of more than 30,000 feet. To obtain wind velocities and directions at various altitudes we made about 400 pilot balloon observations. These were of immediate use in determining the advisability of making flights, but their significance is far greater, for they in all probability will throw most valuable light upon atmospheric circulation in high southern latitudes. An interesting 40-day continuous record, taken during the last of our stay, provides in detail temperature, pressure and humidity at various levels.

Living upon a great ice shelf, we of course were curious as to how far below us was the solid land. Soundings with a sonic depth finder in the Bay of Whales close to Little America gave a depth of about 1600 feet, others to the south and east between 900 and 1000 feet. Other hydrographic work included study of sea life, and depositing message bottles, the recovery of which may some day add to our knowledge of Antarctic currents.

In addition to the meteorological temperature records, the expedition came away with data on the temperature of the ice barrier itself in relation to its physical makeup. Readings below the surface, checked against air temperatures and heat of sun, showed many interesting changes with the varying of the seasons. These records were made in snow tunnels, snow huts, crevasses, and at other subsurface locations where sun and air penetration might be expected to have an effect, or the extent of conductivity of the snow might be checked. Conditions at Little America gave splendid opportunity to measure the dust content of the air, which was determined to be about one half that found over the Pacific Ocean.

With the uniformly low air temperatures—almost never above the freezing point—it is rather surprising to examine figures obtained by our black bulb thermometer, insulated to register the amount of heat radiated by the sun, and find that it went as high as 115 degrees Fahrenheit above zero. A rule of thumb indication of the power that can be exerted by the sun in this bleak land was given by a black tarpaulin fifteen feet square, which sank nine inches into the snow in two sunny days.

Whenever I discuss with strangers the discovery of new territory by the Byrd Antarctic Expedition, I brace myself for the inevitable inquiry, "What use is it, now that you have found it?" Always I reply that whatever man finds, he finds a use for. This application of new knowledge to human needs or wants may require a short time, or it may require a century or more—but it inevitably comes.

Flying over the South Pole has become something of a commonplace. In the late 1970s, Air New Zealand began sightseeing flights from Auckland and Qantas began flights from Sydney. Senator Harry F. Byrd, Jr., of Virginia, a nephew of the Admiral, was scheduled to fly over the pole last November 28 with geologist Laurence M. Gould, who was second in command on the original Byrd Expedition, to celebrate the fiftieth anniversary of the Admiral's South Pole flight. The crash of an Air New Zealand plane that day on Mount Erebus in Antarctica caused a 24-hour postponement of the senator's flight.

# THE TROUBLESOME NOTION OF EVOLUTION

At the start of this century, when *Natural History* began publishing, the *Origin of Species* had been in print for forty years. But the idea of evolution was still a controversial one.

In scientific circles, the debate was on how evolution occurred. During the time covered by these articles (1913–1926), some scientists supported the theory of natural selection, others believed evolution occurred through large-scale mutations, and yet others saw evidence for natural laws that governed the overall direction in which evolution progressed. At the same time, experimental biology was a growing new field. Thomas Hunt Morgan, with his experiments with fruit flies, was revealing the complexity of the mechanisms of inheritance, and gaining the recognition that would win him the Nobel Prize. Paleontologists were continuing to collect and catalog fossils and interpret the record they uncovered.

The research, disagreement, and debate marked a prelude to the development in the 1930s and 1940s of a scientific consensus on evolution, which brought together, in a coherent theory, work in paleontology and genetics and a new statistical treatment of evolving populations. In this "modern synthesis" the two main ingredients were variation (random small-scale mutations) and natural selection.

These theoretical developments are not, of course, the whole story. The idea of evolution had its impact on the larger culture outside the laboratory and the museum. W.D. Matthew, for instance, managed to see a clear, progressive evolution in human morality. In 1920 he was convinced of the moral superiority of his contemporaneous moderns to even the heroes of the past. Matthew's ideas may seem quaint, but Henry Fairfield Osborn's notions of racial superiority are far from quaint. They are frightening, particularly because Osborn was not alone in his belief in the supremacy of whites, indeed of northern European whites. A number of other scientists shared such views, and they did not keep their ideas within ivory towers. Two years before Osborn's article, Congress passed, with considerable scientific support, the Johnson-Reed National Origins Act of 1924, setting up immigration quotas that favored northern Europeans.

To follow up all these articles, to bring evolutionary theory up to date, to trace the cultural impact of evolutionary ideas up until the present would require volumes. Today, the modern synthesis is itself being challenged, and the cultural ferment continues. Religious opposition to the idea of human evolution has never ceased, the innate endowments of human beings of different skin colors are still debated, and violent arguments continue over how much of human behavior and culture evolutionary theory can explain.

# A GREAT NATURALIST
# ALFRED RUSSEL WALLACE, 1823-1913

By HENRY FAIRFIELD OSBORN

THE nineteenth century in Great Britain, the Victorian Age, will be compared in history with the greatest intellectual periods in the history of Athens, of Rome and Florence. Brilliant as were England's achievements in art, literature and the spreading of civilization, her achievements in science outshine them all. No country has ever produced such a constellation of stars of the first magnitude in the same brief period of time, especially in the sciences of geology and biology. The dominant figure of course is that of Darwin, whose influence upon the world of thought is to be compared with that of Aristotle only. Anticipating and surrounding Darwin were members of an unrivaled group of men, beginning with Sir Charles Lyell, a geologist, and including Sir Joseph Hooker, the botanist, Alfred Russel Wallace, the naturalist, and Thomas Henry Huxley, the anatomist and natural philosopher.

Wallace, the last survivor of this remarkable group, died on November 7, 1913, in the ninety-first year of his age and the sixty-fourth year of service and discovery. He followed by only a few months another member of the group, Sir Joseph Hooker, who was present at the Darwin celebration at Cambridge in 1909, the centenary of the birth of Darwin.

Because the fame of Wallace rests chiefly on his codiscovery with Darwin of the theory of natural selection he is sometimes thought of as Darwin's contemporary but he was actually fourteen years younger and made the discovery of natural selection twenty years later than Darwin. He was always the first to recognize Darwin's seniority and leadership. In his remarkable journeys in South America and in the Malay Archipelago, filling the years 1848 to 1862, Wallace was influenced by Darwin's classic work, best known as the *Voyage of the Beagle.*

The simultaneous publication of the law of natural selection independently discovered by these two great naturalists was followed on the part of Wallace by a lifetime of devotion to this chief principle of Darwin's special theories of the causes of evolution. While Huxley was the stalwart defender of the evolution theory and of Darwinism in general without committing himself to either of Darwin's special interpretations of the theory, Wallace devoted himself continuously to the support of Darwin's special hypotheses. Yet almost from the first he differed from Darwin in some very important particulars. He never could bring himself to believe that the mind and spirit of man were the results of the same evolution process as that which had developed his bodily structure and that of all the lower orders of animal creation. As early as 1864 he advanced the hypothesis that so soon as man learned to use fire and make tools, to grow food, to domesticate animals, to use clothing, and to build habitations, the action of natural selection was diverted from his body to his mind and that thenceforth his bodily form remained comparatively stable while his mental faculties improved.

Five years later Wallace had definitely broken away from Darwin's conceptions with regard to natural selection and developed the opinion that this law is wholly inadequate to account for several of the bodily as well as physical characteristics of man, such as his soft and sensitive skin, his speech, his color-sense and his mathematical, musical and moral attributes. He drew the inference from this class of phenomena, that a superior intelligence has guided man's development in definite directions and for special purposes, just as man guides the development of many animal and vegetable forms.

Wallace like Darwin enjoyed the closing years of his life in the quiet surroundings of a beautiful English country home, and continued even to his ninety-first year to be a great force in the world's thought. His powers as a writer were prodigious and in rapid succession in his later years he brought out his volumes *My Life,* the *Wonderful Century,* the *World of Life,* and *Social Environment and Moral Progress.* In the *World of Life* he no longer believes in the Darwinian explanation of natural selection as adequate to account for the wonderful adaptations which we find in the animal world. He regards life as "a manifestation of creative power, directive mind and ultimate purpose." He thus returns in his later years to the teachings of his boyhood, to those which prevailed before the publication of the *Origin of Species.* His final creed is found in one of the closing paragraphs of the *World of Life:*

> In the present work I have endeavoured to suggest a reason which appeals to me as both a sufficient and an intelligible one: it is that this earth with its infinitude of life and beauty and mystery, and the universe in the midst of which we are placed, with its overwhelming immensities of suns and nebulae, of light and motion, are as they are, firstly, for the development of life culminating in man; secondly, as a vast schoolhouse for the higher education of the human race in preparation for the enduring spiritual life to which it is destined.

*APRIL 1915*

# MORGAN'S "HEREDITY AND SEX": A REVIEW

### BY E. G. CONKLIN

THIS book is the outgrowth of the Jesup Lectures for 1913 which were given by Professor [Thomas Hunt] Morgan at the American Museum of Natural History. It is a very difficult thing to make a book interesting to the general public and at the same time valuable to scientific readers, but this difficult task Dr. Morgan has accomplished in an admirable manner. His book is a work of extraordinary interest to the intelligent layman and at the same time one of great value to professional biologists, and its wide success is attested by the fact that the first edition was exhausted and a new one issued within a year.

With remarkable clearness and brevity the author presents the facts of the complicated structure of the germ-cells, their origin, maturation, union in fertilization, the way in which sex is determined and the mechanism of hereditary transmission. He accepts unreservedly the view that sex is determined at the time of fertilization; if the egg is fertilized by one type of spermatozoön a male is produced, if by the other type a female results. He also holds that the evidence is "almost convincing in favor of the view that the chromosomes are the essential bearers of the hereditary qualities." In favor of the chromosomal theory of heredity he presents evidences drawn from cytology, from experiment and from *sex-linked* inheritance. The latter is a type of inheritance, first clearly distinguished by Morgan, in which characters are transmitted to male or female offspring in exactly the way in which certain chromosomes are transmitted. On the other hand in *sex-linked* inheritance "the secondary sexual characters appear in one sex only and are not transferable to the other sex without an operation."

After discussing the principles of inheritance discovered by Mendel the author presents the results of his own work on the inheritance of sex-linked characters in the fruit fly. This is perhaps the most important part of this book, as it is one of the most valuable contributions to the study of heredity which has been made in recent years. The author concludes "that when inheritance factors lie in different chromosomes they freely assort and give the Mendelian expectation; but when they lie in the same chromosome they may be said to be linked and they give departures from the Mendelian ratios." Inasmuch as factors which usually lie in different chromosomes may sometimes come to lie in the same chromosome, Morgan has suggested that when the maternal and paternal chromosomes pair in the maturation stages

RALPH BARTON

*Among the statesmen present was always William B.*

of the egg or spermatozoön, the chromosomes of each pair may actually fuse at certain points where they cross each other and thus portions of the chromosomes with their factors exchange places. With this interesting hypothesis as a basis he has been able by means of his breeding experiments with fruit flies to plot the location of particular inheritance factors in individual chromosomes. This work, although in many respects hypothetical, is well supported by evidence and it is probably the most important work ever done on the "architecture of the germ-plasm."

This book was written on the firing lines, as it were, of biological science and it deals with many matters which are not finally settled. It is inevitable that such a book should encounter differences of opinion on the part of other investigators in this field, but the author is peculiarly happy in his manner of presentation. He writes as one who is convinced and yet tolerant and open-minded. His style is brief, keen, attractive, and best of all in a scientific work he shows a thorough, first-hand acquaintance with the phenomena described, and sound judgment and good imagination in dealing with them.

# PROGRESS

A Drama of Evolution in Five Acts

BY T. D. A. COCKERELL

*Argument*—Evolutionary progress has not flowed in a single continuous stream from amoeba to man; it has branched and branched again, so that the ramifications are more numerous than the mind can follow. The most significant new branches have not arisen from the ends of the old ones, but as entirely new departures from the main trunk of the tree. Thus each great innovation, full of meaning for the future, has at first appeared to contradict the teachings of the past.

In these modern days, teachers, professing to hold the learning of the past, are telling us that we "cannot change human nature": that every wicked and vicious thing has its roots in nature, and however much it is to be deplored, it must be endured. This attitude is one of the deep fundamental causes of the present war. Let us learn indeed from the past, that significant progress is always possible, but through narrow paths, which to our eyes, blinded by the light of custom, seem dark and dangerous. Hazarding these byways, many of us must fail, but the few who succeed will win for the human race the rich prizes of the future. This is not mere sentiment; it is the teaching of science and of universal experience.

## Act I

*Beneath the waters of the ocean. Seaweeds, lobsters, crabs, mollusks, etc.*

*Time, Late Cambrian*

*Enter* AMPHIOXUS, LARVAL TUNICATE AND BALANOGLOSSUS

AMPHIOXUS. We are not much to look at, but we are
All in the way of progress.
Our backs are stiffened by a notochord, and all above
A slender nerve cord runs from fore to aft,
Prophetic of a brain. This tiny spot, this little speck of black,
Will some day be a pair of eyes, to knowingly survey the world,
While these gill slits, ranged on each side, already serve
To liven us with oxygen, gleaned from the waters flowing through them.
All in the way of progress to be vertebrates, and in days to come
Perchance, some creature with a soul.

LOBSTER. All in the way of progress! Are you mad?
I tell you, sirs, the progress of the past has not been thus.
In years so many that to count by millions is fatiguing,
In all the ages since the Cambrian dawn, and all the unknown times before
Was never such a thing.
Your nerve cord dorsal! Do you know
You're upside down? Clean topsy-turvy, and this somersault
You say is progress! You think the learning of the past
Is nothing. The spirit of creation, giving lobsters, crabs and snails,

Fine worms, starfishes and sea cucumbers: all this
Can now be set at naught, and you, clean upside down,
Will lead the van of progress!

[*All the animals laugh inordinately.*]

OYSTER. Our good crustaceous friend speaks truly; let me ask
Where would your progress take you?
What is a vertebrate, and what this thing
You say might have a soul?
No science teaches of such things, nor any story of the past;
A crab we know, a shrimp we know, a limpet is concrete and real,
But this absurdity you tell of, what is it?
A recollection of a dream that dreamed of dreams,
A twist of thought so meaningless that it is less than nothing.
Come friends, forsake your quest and be like us!

SEA URCHIN. Moreover, just consider how you look:
Small, soft and pallid or mud-colored.
No legs, no spines, no shell, no gaudy hues
To make you seem in fashion, and in form
To mix in good society.
In truth there's nothing in your favor save the claim
That you mean progress, and that notion's so absurd
It serves but to condemn you.

TUNICATE. Alas! What have we come to
In this mad quest for progress?
I fear 'tis as our friends declare, we're topsy-turvy,
And in seeking what is not, have lost what is.
For me no hope of excellence is left, no hope of being fit to stand
With lobster, snail or maritime cucumber. Yet I may show
My penitence in just one way, I may forego
These modern airs and change into a humble squirting sac.

BALANOGLOSSUS. And I also must hide my new conceits,
And simulate a worm. I pray you friends,
In charity pretend I am a worm.

AMPHIOXUS. Oh, comrades of such slender faith,
O'ercome by tory talk,
No future lies in store for you
But one dull round to walk.
Invertebrates you cannot be,
Nor vertebrates withal,
Alone among the beasts of sea,
The laughing stock of all.
My children are the heirs of time,
My sons will rule the earth,
When vertebrates come to their own,
And human things have birth.

---

*OCTOBER 1916*

# THE LAWS OF SPECIES FORMING

BY DAVID STARR JORDAN

SOME years ago I ventured the statement that taking any given species of animal, the nearest related form would not be found along with it, nor at a great distance, but on the other side of some barrier which prevented intermingling.

This fact is almost self-evident, as far as the higher animals are concerned. We very rarely have any difficulty in determining the separate species in any given region. For this reason those naturalists who read the proposition have accepted it. Dr. J. A. Allen, one of the highest authorities on birds, went a little further and named it "Jordan's Law." But it existed in the nature of things before it was mine, and I can be credited with its ownership only for the sake of convenience in the discussion of the many ways in which life manages itself, which we call natural "laws."

In discussing the origin of species, we premise first that species in nature exist—but not as closed categories. They arise through the perpetuation by heredity of variants which are cut off from the original species by some sort of barrier of land or sea, of temperature or climate, of food or enemies. Once cut off, their inadaptive excrescences are pared away by selection, and at last the new species, as well as the old, comes to fit its environment as the river fits its bed.

As regards the vertebrate animals this is the origin of species. We can prove it in thousands of cases, as surely as we can prove anything by experiment when nature lays down its conditions. While now and then "mutations" or discontinuous variations occur, especially in domestic races of mixed origin, I do not know of a single species of vertebrate animal which could even hypothetically be supposed to have originated from a mutation.

Among the different races or variants of birds, none is recognized by name, or as having permanence, by competent ornithologists, unless these variants have a geographical basis. Subspecies are therefore geographical races, and these are the stuff that species are made of. The word geography should not be construed too literally; one does not need to go far up a mountain side, or into the depths of the sea, to find a condition of things radically different from those at sea level, on land, or in the ocean.

If there were one-thousandth part of the evidence for the origin of species by mutation that is shown for the origin by separation, the theory of de Vries would have standing in science. But to show that species arise in general through separation by barriers is not to exclude any other influence whatever. We know of no species however, which is not the product of internal influences —heredity with variation—modified by the external limitations arising from selection and isolation. Whatever else may be a factor in the formation of species in nature or in domestication, from these four we can never escape—heredity, variation, selection, and segregation.

---

*JANUARY/FEBRUARY 1920*

# SIXTY YEARS OF DARWINISM

## A LOOK BACKWARD AND FORWARD

Molluscan shells of the sea-beaches and ocean beds of the millions of years of the past suggest that evolution works gradually and continuously along definite controlled lines—A field for future research

BY AMADEUS W. GRABAU

DARWINISM then, in the sense of the modern followers of Darwin, the Neo-Darwinians as they have been called, is the doctrine that the environment destroys the unfit and preserves the fit—natural selection takes place; that the essence of fitness is adaptation to the conditions of existence—the best adapted will survive and hand on to their offspring those characters which have made them fit; and finally, that these characters arise as the result of fortuitous variation; that is, variation apparently uncontrolled by any known law.

But the environment, too, is constantly changing; the Garden of Eden becomes a desert, roses bloom on the site of a prehistoric Sahara. "There rolls the deep, where grew the tree. . . . There where the long street roars hath been the stillness of the central sea." Adaptations, which under one environment insured survival, under changed conditions spell death. The *Megatherium*, the last of a long line of ground sloths, and well adapted to the food of its native haunts, became enfeebled as this food supply diminished in consequence of a change in climate, and so fell an easy prey to its chief adversary, the saber-toothed tiger. The sabertooth, in turn, fitted with tooth and claw adapted to hunting and stabbing to death those slow-moving thick-skinned herbivores, faced starvation when the last *Megatherium* was devoured, because from over-specialization this cat had lost plasticity to adapt itself to the swifter-footed grazing animals which formed the prey of its more agile cousins, the true tigers, the lions, jaguars, and the other great biting cats which still survive where man, their principal enemy, permits it.

The struggle for existence denies opportunity to the unfit; always and everywhere the fittest alone survive, always and forever the weak go to the wall. That is Darwinism pure and simple. Hope lies in a changing environment—the fit today become the unfit tomorrow. The law of the jungle cannot survive the jungle—the militarist cannot survive in a nonmilitaristic age—nor the Bolshevist the restoration of the reign of reason. When the environment of common sense is reestablished, the worker and the capitalist each again will find his place, and the advantage to all will be seen in the development of those qualities and powers which will make the unfit of today fit to fill their proper place in the united army of struggling humanity. That, too, is Darwinism.

But, I repeat, Darwinism is not the sole factor in evolution, at least not in the belief of many students of nature. To begin with, the value of fortuitous variations as a basis for selection is seriously questioned by many who cannot accept minute changes in form and character as of sufficient import to determine survival. Color harmony with the surrounding habitat may protect the animal by deceiving its enemy, the camouflaged ship has a chance to escape the lurking submarine, where the one not thus protected will be lost, but such adaptations are not small, they are large variations from the normal. A single stripe, the first step in the production of the protective design upon the vessel, will not serve the purpose of deceiving the enemy any more than a single green spot would serve a brown *Mantis* upon green grass, or the first step in the development of a pattern which makes the palatable butterfly resemble the distasteful one, deceive the hungry bird. But fortuitous variations are first steps, they are minute beginnings in the production of a serviceable whole and as such, cannot serve the purpose of the finished product. To have selective value the variation must be adequate; to become adequate it must either arise suddenly, or develop by cumulative additions in the proper directions without reference to immediate selectivity.

The attention of naturalists has of late years been directed to those larger and apparently sudden variations which are seen to arise occasionally in nature, and which are familiarly known as sports. The phenomenon is illustrated by the short-legged ram, which appeared suddenly in Massachusetts in 1791, and from which the race of ancon sheep, once prized because of their inability to jump fences, descended. Darwin at one time attached great value to such sports, but later on relegated them to a place of secondary rank.

But when the Dutch botanist Hugo de Vries discovered sports of the evening primrose (*Oenothera lamarckiana*) in a field not far from Amsterdam, and found by experiment that these forms bred true to type, that is, they were not fluctuating, but had constant new characters, the attention of the scientific world was again directed to this phenomenon, and careful breeding experiments became the order of the day. De Vries and most of his followers became convinced that not by minute fluctuating variations about a mean, but by sudden jumps, was progress made. From causes still unknown, the elementary characteristics of an animal or a plant now and then undergo a sudden rearrangement, much as the colored glass particles in a kaleidoscope are suddenly rearranged to form a new pattern, and this new organic pattern constitutes a new elementary species. Such an abrupt rearrangement of characters De Vries called mutation, others have called it saltation, and it is generally thought of as a process uncontrolled by any known law. To the De Vriesians the new elementary species thus produced are the only variations from the type which count. They alone are subject to natural selection; they alone mark the steps in the progress of the organic world.

*MARCH/APRIL 1922*

## RECENT DISCUSSIONS CONCERNING EVOLUTION

To the discussion regarding evolution, precipitated by the attack of the Hon. William Jennings Bryan upon the doctrine in question, several members of the scientific staff of the American Museum have contributed. In The New York Times of March 5 President Osborn made a thoughtful reply to Mr. Bryan, insisting that "truth is truth and must prevail" and expressing the opinion that if Mr. Bryan "with an open heart and mind, would drop all his books and all the disputations among the doctors and study first-hand the simple archives of Nature, all his doubts would disappear; he would not lose his religion; he would become an evolutionist." In The New York Evening Post of April 1, Dr. William K. Gregory, curator of comparative anatomy, showed the vulnerability of Prof. Francis P. Le Buffe's assertions, particularly as applied to the central exhibit of the hall of the Age of Man, in the American Museum. Dr. Gregory has also given a number of addresses recently on different phases of evolution. Before the Wagner Free Institute of Science in Philadelphia he delivered between March 4 and March 25 four lectures on "The Evolution of the Human Face," on March 29 before the Galton Society he presented "Notes on the Origin and Classification of Homo sapiens," and on April 10 before the New York Academy of Sciences a paper which he had prepared with the collaboration of Dr. Dudley J. Morton, entitled "Has the Human Foot Been Derived from a Gorilloid Type?" Dr. Robert Cushman Murphy, associate curator of the department of ornithology, spoke before the Park Church in Elmira—a Congregational church founded by a brother of Henry Ward Beecher—on "Bryan and Evolution," in which he pointed out that science has no quarrel with religion and then proceeded to present from many angles the evidence for evolution.

The Darwinian and the follower of De Vries have a common starting point—they both concern themselves with adult individuals. The voice of the elder Agassiz, crying in the biological wilderness of the early half of the last century, and exhorting naturalists to pay attention to the immature stages of animals and plants—those stages which lie between the embryo and the adult—has never reached their ears, or if they heard, they did not heed. But a disciple who followed the master in his wanderings through the underworld, where dead and forgotten generations of animal life had written their own epitaphs on tablets of stone, listened and learned and, by patient search among the ancient life records, became convinced that the new faith into which he had been baptized, pointed the true way to biological salvation. Alpheus Hyatt proved what Agassiz preached, that the immature stages of an animal's life history furnish the key to its racial history, that the young animal repeats the adult characters of its ancestor which lived in the immediately preceding geological period, and that this ancestor in turn had repeated in its own youthful stages the characteristics of a still earlier member of the tribe. Agassiz did not accept the doctrine of evolution, but Hyatt recognized the philosophic bearing of the facts uncovered by his researches. Step by step, the history of each individual type carried him backward in the history of the race until the beginning was reached. Down the long corridor of time he passed and took his pupils with him. Eagerly each new inscription was scanned, and each pupil selected that which to him seemed most promising, and then began to unwind the long record of ancestral achievement. And whenever the way seemed long, and their courage began to fail, new vistas would open, and the pursuit regain new vigor. And in this quest it became increasingly more apparent that variation was not fortuitous nor indefinite, but controlled along definite directions. To be sure, the controlling force has not been revealed, but the very definiteness of the variation leaves no doubt as to the existence of such a control.

# THREE-TOED HORSES

## A Fossil Record that Provides Direct Evidence of Evolution

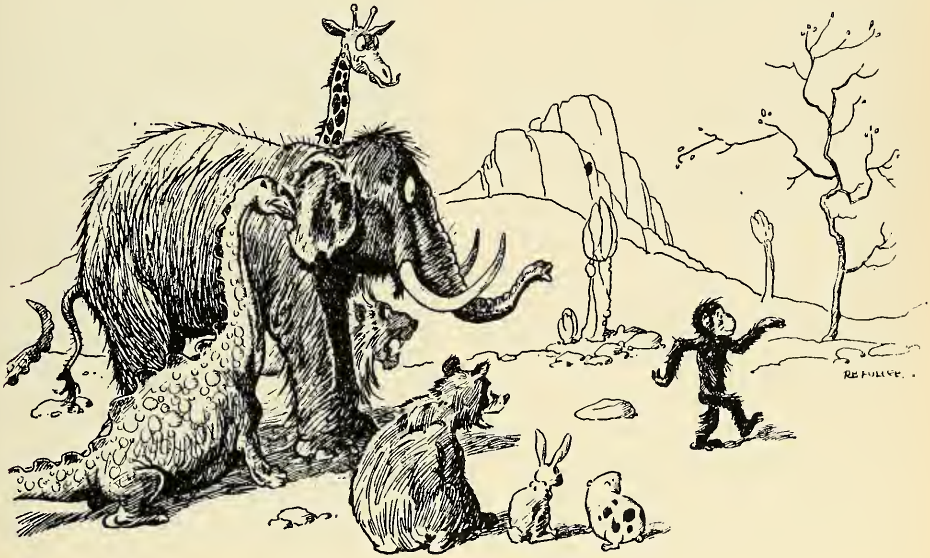
By W.D. MATTHEW

WHAT were these three-toed horses anyway? Why are they so important or so interesting that literally thousands of scientific papers have been written about them. Briefly, they are thus important because they can afford one of the best records by which to test the truth of the theory of evolution.

The theory of evolution—commonly but wrongly called "Darwinism"—is an attempt to explain the present diversity of living beings and their various resemblances and differences in structure as due to their descent from common ancestors and the slow, gradual changes in each race in adaptation to its particular mode of life. The doctrine of natural selection—Darwinism properly so called—gives as the cause of these changes the gradual accumulation through innumerable successive generations, of such minute differences as we find always exist between individuals and tend to be inherited by their offspring.

All the evidence for evolution found in the anatomy and structures and habits of animals, in their relationship and distribution, in the growth and development of the individual, in the breeding and selection of domestic animals and of plants, and in the so-called "experimental evolution" which has converted into a science the practical knowledge of the breeder, is, after all, indirect evidence. However uniform its inferences, however overwhelming its weight, however perfectly and admirably it explains innumerable details of structure and habit for which no other reasonable explanation can be found, it would be as nothing if palaeontology were against it. If the actual remains of fossil animals showed that they had always been as they are now since they first appeared on the earth, then, indeed, we would have to sweep aside the beautiful theory of evolution with all the exquisite perfection of its explanations of every tiny detail in the complex structure of the higher animals, as an iridescent dream. We would have to say to the anatomist, to the embryologist, to the experimental evolutionist: "Oh, yes! Your interpretations and analogies and experiments are ingenious and interesting, but you can't prove evolution by them for they are in conflict with the plain facts. The record of what actually has happened shows that species *did not* come into being that way. They were created in the beginning just as they are."

But the fossil record, this plain, direct, and unalterable record of what *did* happen during the past history



*The upstart*

of the earth, *does* prove evolution, and wherever it is complete enough, it proves it so directly and conclusively that it removes it from the category of theories to that of facts. It is, indeed, a very incomplete and fragmentary record. It owes its preservation and existence rather to the chapter of accidents than to the normal cause of circumstances. But, whenever there is anything approaching a consecutive detailed record of any race or type of animal, it becomes perfectly evident that the race or type has not come into existence in its present form, but has changed through numerous small or minute gradations from an original type which is hardly or not at all distinguishable from the original form that gave rise to other races or types now widely different.

The best evidence of this sort is to be found among the invertebrates, especially among mollusks, which include many cases where the gradual change in a race can be followed by numerous specimens from each stratum.

But while the evidence of these invertebrates affords conclusive proof of evolution to the palaeontologist, it is not always convincing to the layman. Many people may be willing to admit that one species of clamshell has changed gradually into another, but they will deny vigorously that a horse and a tapir are descendants of a common ancestral stock, and angrily resent the imputation that they themselves are blood relatives of the chimpanzee and the gorilla. Such a position is illogical, if they only knew it, for if the proofs of evolution in the anatomy of the lower animals are shown to be in accord with the facts of their past history, then the much stronger evidence in the anatomy of the higher animals must mean the same thing in their case. But it is natural enough, for the objections to evolution center around the descent of man, and the average anti-evolutionist will hardly see that his traditional view is endangered by anything so remote as the humble mollusk.

The evolution of the horse, however, comes near enough home to shake his confidence if he is opposed, or to assure his belief if he is in favor of the theory of evolution. It is not the record in which we are most interested, namely, that of the evolution of our own race. But it is that of one of the most familiar domestic animals, the changes in the structure of the skeleton are obvious and the reasons for them easily understood, and the record of the evolution of the race is a fairly complete one so far as it goes.

The present distribution of the horse family, aside from domestic horses, is limited to Africa and central Asia. In the latest geological formations, however, of the Pleistocene epoch, we find fossil remains of various species of horse in all parts of Europe, Asia, and Africa, North and South America. These species are all closely related to the existing horses, one-toed, and with teeth entirely similar to the modern species.

In the next preceding epoch, the Pliocene, we find fossil horses both in the Old World and the New, and some of them in the later part of the Pliocene of Europe are also closely related to the modern horse and are placed in the same genus, *Equus*. In the Lower Pliocene we find three or more genera all evidently related to the horse but of smaller size, with the side toes less reduced, completely formed in some species. In the Miocene there are numerous species, all of them with the side toes complete but small and slender, seldom reaching the ground. They average about the size of a donkey, and their teeth are shorter crowned than in the later horses. In the Oligocene the horses are still smaller, averaging about the size of a sheep, the side toes are less reduced so that they reach the ground and help support the animal, and the teeth are comparatively short crowned with simpler pattern. In the Eocene the horses are still smaller, averaging about the size of a terrier dog, their side toes are quite large, and in the forefoot there is a fourth digit, so that these are known as "four-toed horses." The teeth are still shorter crowned and simpler in pattern.

These are merely the outstanding stages in a long succession of intermediate gradations that connect the modern horse with the little four-toed *Eohippus* of the Lower Eocene. Each gradation is found in its appropriate geological stage, and not earlier or later. The changes and gradations are seen just as clearly in every bone of the skeleton as in the feet and teeth, and the gradual evolution of the race is thus shown by direct and overwhelming evidence. You may indeed, if you choose, declare that each successive gradation was independently created. Direct proof on that point is not at hand; the genetic continuity rests upon inferential evidence. But that the race as such evolved gradually, little by little, through the millions of years of the Tertiary period, is a matter of plain fact and record.

It is equally a matter of record that the now diverse types of tapirs and rhinoceroses evolved gradually from a common ancestral stock with the horses; and that all the records of other races of mammals show them converging backward in time toward a common stock. The *Eohippus* is by no means as different from man as is the modern horse and he is far closer in every detail of his construction to the Eocene representatives of the group to which man belongs (the Primates) than he is to man. All other races of animals display the same convergence toward a common ancestry in every detail of the teeth and feet and skeleton.

The evolution thus shown as a fact of record in certain portions of the history of various races which have been preserved to us in the history of life, appears to be a sure inference as applied to the whole, supported as it is by the community of fundamental structure that prevails through the whole living world, by the obvious adaptation of each race to some particular habit of life, by the proof that natural selection can and must operate to bring about changes in the structure of the race in adaptation to its habits. If we recognize that the records, where they are preserved, show evolution to be a fact, we cannot logically refuse to admit it in the undiscovered portions of the record, upon the force of the immense amount of inferential evidence in its favor, and, in conclusion, because it is the only real explanation of life, the only one that rests upon natural law.

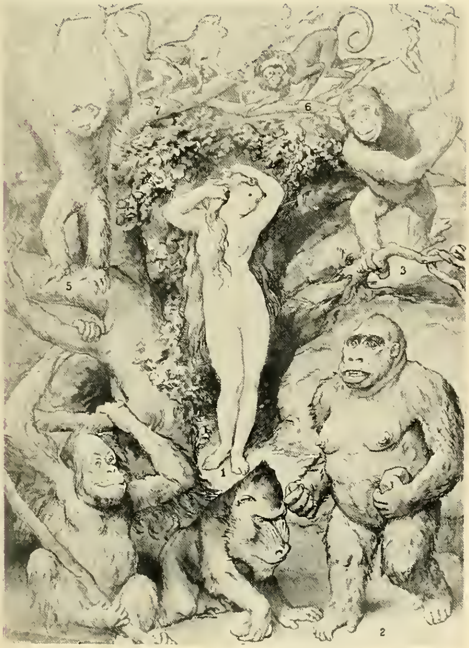
*SEPTEMBER/OCTOBER 1920*

# SOCIAL EVOLUTION: A PALAEONTOLOGIST'S VIEWPOINT

### BY W. D. MATTHEW

IN a recent address a well-known newspaper editor is quoted as saying: "To me the lack of proof of any improvement of the human mind as far back as history goes is the most impressive proof of the creation of the human mind, against the theory of evolution."

There is, however, another aspect of the human mind in which I think there is very clear evidence of progress. This is the moral or ethical as contrasted with the intellecual side. Here, I think, one may see both in precept and in practice, a marked advance, a steady improvement, fairly continuous upon the whole, and resulting in a notable contrast between the standards that we see represented in the writings and actions of early peoples, and those which prevail today. I use the term "moral qualities" in its broadest sense to include all those inhibitions and restraints, those actions and thoughts which prefer the ultimate advantage of the individual to his present advantage, which sacrifice a lesser individual benefit for the greater race benefit, which tend to the development of social life and more elaborate social organization.



*"Apotheosis of Evolution," by E. Haeckel and G. Max*

Consider the moral standards of the Old Testament as compared with those of today. How would we regard David, "the man after God's own heart"? An able warrior, no doubt, clever, active, well-meaning, magnetic, a good fellow on the whole, but surely something of a weak brother. How would he measure up with Washington, with Lincoln, with William Pitt? "The righteous man sweareth an oath and keepeth it even though it be to his own hindrance." Surely that is not so remarkable in the modern righteous man as to call for special and rather surprised commendation. "An eye for an eye and a tooth for a tooth." Are these the ideals of our modern treatment of criminals? Rather, one would say they are the standards that prevail among the criminal classes themselves.

Or, take the matter of self-control, of the regulation and management of one's daily life and habits. How many of the kings and leaders of olden time were able to withstand prosperity, to refrain from indulgences that shortened their own lives and ruined the prestige of their dynasties in one or two generations? Does not the whole of ancient history leave one with an impression of gorging and feasting without regard for the morrow, of snatching at the pleasures of the moment often at a terrible future cost? Contrast with this the sober regularity of the average civilized man of today, the diligence and abstemiousness of most modern leaders, political or financial. It is useless here to cite examples, but I cannot but be impressed by a marked difference in averages.

Now all this is exactly what we should expect on the Darwinian theory. Five thousand years, the most that we can give to such historical records as bear upon the present problem, is too short a time, if measured by the recorded rate of progress in evolution, to produce any perceptible change in the physical structure of man. And his intellect, based as it is upon the physical structure and complexity of his brain, should show a similarly slow rate of change. The specialist distinguishes with difficulty between the skull of an extinct horse of the early Pleistocene and that of its modern descendant. Whether we estimate the length of the Pleistocene at 100,000 years or, as high modern authorities insist, at a million or more, it is obvious that the evolutionary change in this race during five thousand years would be imperceptible. And this is equally true of any other race of mammals of which we have a good evolutionary record. By this measure one would not expect to see any appreciable evolutionary change in the brain and intellect of man since history began. On the contrary, if a marked and obvious improvement in brain or other physical characters had taken place during that time, it would constitute an exceptional case of abnormally rapid evolution, calling for explanation.

On the other hand, the moral qualities may be viewed as partaking rather of the nature of fixed habits, viewpoints, instincts, not directly correlated with the complexity of the physical brain structure, and like other instincts and habits, much more variable and more rapidly modifiable than the physical structures of the body and functions directly dependent upon them.

Natural selection will seize upon those variations which are most useful for the individual or for the race, and will accumulate them in proportion to the rate at which they can be modified. Obviously the moral qualities of man have for many centuries been at least as important for his social advantage as any intellectual or physical superiorities for his individual advantage. Because of their being more rapidly improvable, the principal advance has been in these qualities. Indeed, I find it difficult, as a palaeontologist, to look upon human history as other than a splendid record and display of the operation of natural selection applied to races instead of individuals, and resulting in social, not in individual, evolution. This process of social evolution with its rapid changes leading often to an astonishingly elaborate and perfected organization, is by no means confined to man. It is illustrated again and again, in various stages of its development, throughout the animal kingdom. The traces of its existence in extinct races are naturally obscure and difficult to decipher; we are dependent upon observation of living animal societies and inferences as to the evolution of their habits.

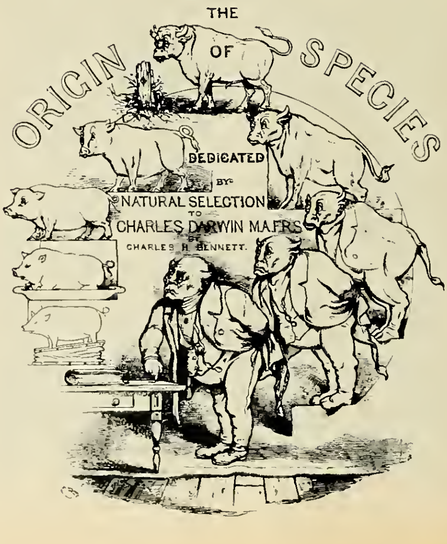
From observation and comparison of such modern social communities, one may perhaps draw certain conclusions as to the trend and limits of social evolution, and apply them to the future of our own race.

(1) Marked tendency to a progressive uniformity and fixity of type and habits. In the early stages of social development one may observe a considerable flexibility and individual initiative, a greater variation in the action of the individual under given conditions. In the more elaborated types of social life the individuals of each class appear to think, act, and feel alike and to perform their respective duties in a more uniform and automatic way.

(2) Although amazingly precise and elaborate social relations are found among lower animals—insects especially—yet the complexity of the community life appears to be limited in many ways by the intelligence of the individual. None of the higher animals has carried social life to the extremes of precision and exact coördination that we observe among the social insects; in none of them is the individual so far sacrificed for the benefit of the race. Yet the complexity of the social life of the higher animals is in some respects greater—in man it is far more complex.

The ultimate result of social evolution would seem to be a precisely adjusted, uniformly acting organization, working with the automatic accuracy of the complex association of cells of which each individual is composed. The degree of complexity which such an organization can attain before it reaches that precise adjustment depends, as I see it, upon the intelligence of the individual units which compose it.

If this be true, we must conclude that once such a finished social mechanism has been perfected, its further progress must be relatively slow. While up to this stage its evolution has depended upon the modifying and perfecting of the moral or social instincts, henceforth it must depend upon the far slower evolution of a higher physical and intellectual type. From the short perspective of human history this phase of physical and intellectual evolution is so slow as to be negligible. We may fairly say that our present trend of social evolution will tend to advance to a civilization far more complex, far more precise in its adjustment, to continually more uniform group-types of individuals, not appreciably higher in intellect but very much higher in morality; to eliminate more and more completely the criminal, the idle, the selfish individual, the unsocial of every type; and to reach finally the goal of altruistic endeavor. This cannot be reached, however, in a generation; such a mechanism involves much higher standards of morality than now exist in the average man, and requires also the elimination of all who fail to measure up to them. But that this process is going on, and has been going on for some thousands of years, I, who read history in the light of palaeontology and evolution, cannot doubt. Nor have I any doubt as to its ultimate outcome, regrettable in some respects, desirable in many others, to the individual who, with growing social instincts, still retains some of the flexibility and impatience of restraint and uniformity that are inherited from his remote forebears of the wild tribes of primitive man. But what will be, will be. We may try to read the future if we will; we cannot alter it.



*JANUARY/FEBRUARY 1926*

# THE EVOLUTION OF HUMAN RACES

BY HENRY FAIRFIELD OSBORN

FRANCE, from the close of the eighteenth century, was the leader in Anthropology, the science of man. In 1875, Armand de Quatrefages, professor in the Museum of Natural History, Paris, delivered a course of elementary lectures on "The Natural History of Man" to audiences of working people in Vincennes. These delightful lectures represent the pre-Darwinian point of view and dwell with emphasis upon the *unity* of human species and upon the intellectual, moral, and spiritual distinctness of man.

In support of his opinion that all the greater and lesser divisions of the human race belong to a single species, namely, *Homo sapiens,* Quatrefages observes: *"Fertility is the law of union between animals belonging to different races* (mixed breeding)," whereas *"infertility is the law when animals of different species unite* (hybridization)." This argument is now known to be invalid; we know that, both in nature and in experiment, many distinct species and even distinct genera of plants and animals occupying over-lapping geographic areas interbreed freely and may leave a long series of hybrid descendants, some of which are highly useful both in plant culture and in animal culture.

If an unbiased zoölogist were to descend upon the earth from Mars and study the races of man with the same impartiality as the races of fishes, birds, and mammals, he would undoubtedly divide the existing races of man into several genera and into a very large number of species and subspecies.

There has been a profound change both in our knowledge of facts and in our theories and conceptions since the time of Linnaeus and even of Quatrefages, through anatomical researches among the Asiatics and Africans. This is the recognition that the genus *Homo* is subdivided into three absolutely distinct stocks, which in zoölogy would be given the rank of species, if not of genera, stocks popularly known as the Caucasian, the Mongolian, and the Negroid:

*Homo sapiens europaeus*—North and south Eurasiatic stock, wavy hair (cymotrichous) with intermediate cross section. Broad- or long-headed. Tall to medium stature. (= CAUCASIAN.)

*Homo sapiens asiaticus*—Extreme East Asiatic stock. Straight hair (lissotrichous) with round cross section. Broad-headed. Medium to tall stature. (= MONGOLIAN.)

*Homo sapiens afer*—African stock. Closely curled hair (ulotrichous), flattened cross section. Narrow-headed. Short to tall stature. (= NEGROID.)

The spiritual, intellectual, moral, and physical characters which separate these three great human stocks are far more profound and ancient than those which divide the Nordic, Alpine, and Mediterranean races. In my opinion these three primary stocks diverged from each other before the beginning of the Pleistocene or Ice Age. The Negroid stock is even more ancient than the Caucasian and Mongolian, as may be proved by an examination not only of the brain, of the hair, of the bodily characters, such as the teeth, the genitalia, the sense organs, but of the instincts, the intelligence. The standard of intelligence of the average adult Negro is similar to that of the eleven-year-old youth of the species *Homo sapiens.* The wisdom teeth of the Negro are erupted at the age of thirteen; the wisdom teeth of *Homo sapiens* are erupted between the ages of twenty-one and thirty, if at all. The young Negress may produce her offspring at the age of eleven; the early maturing Hindoo woman of Caucasian stock may produce offspring at the age of twelve. Hundreds of other differences might be cited. This is not said in disparagement of the Negroid race, which displays many noble qualities of spiritual and moral character, as observed by sympathetic and unprejudiced travelers like Herbert Ward, whose sculpture has also revealed the superb physical development of the native Negro.

The Mongolian is somewhat less profoundly different from the Caucasian than is the Negro. The intelligence and morale of the Mongolian may fully reach the high Caucasian level, as shown in great periods of Chinese history, but his physical development seldom equals that of either the Negroid or the Caucasian, which give rise to the tallest races in the world.

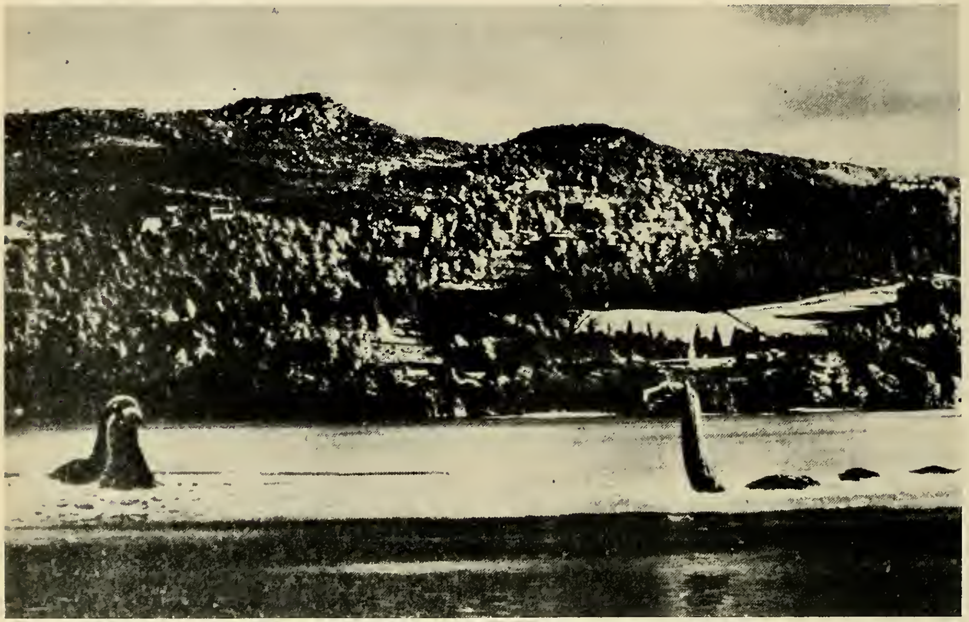
The hair happens to be one of the most conspicuously distinctive and constant features of these three species of man. Skin color is less uniformly distinctive. The Mongolians are yellow to dark brown or bronzed in skin color. The Negroids are generally dark brown to full black. The Caucasians are extremely fair-skinned in the North, light-brown-skinned in the South, very dark-brown-skinned in subtropical Polynesian hybrid branches, like the Hawaiians.

Each of these human species interbreeds with the other and produces a great variety of half and quarter breeds. Thus *inter-fertility is not a bar to specific distinction or even to generic distinction in mammals.* In the family of Bovidae, for a parallel, several genera and species freely interbreed, e.g., our domestic cattle (*Bos taurus*) and the bison (*Bison americanus*).

*NOVEMBER 1934*

# THE LOCH NESS "MONSTER"

BY WILLIAM K. GREGORY



*Two "monsters" in a single loch. A sinful waste of native talent!*

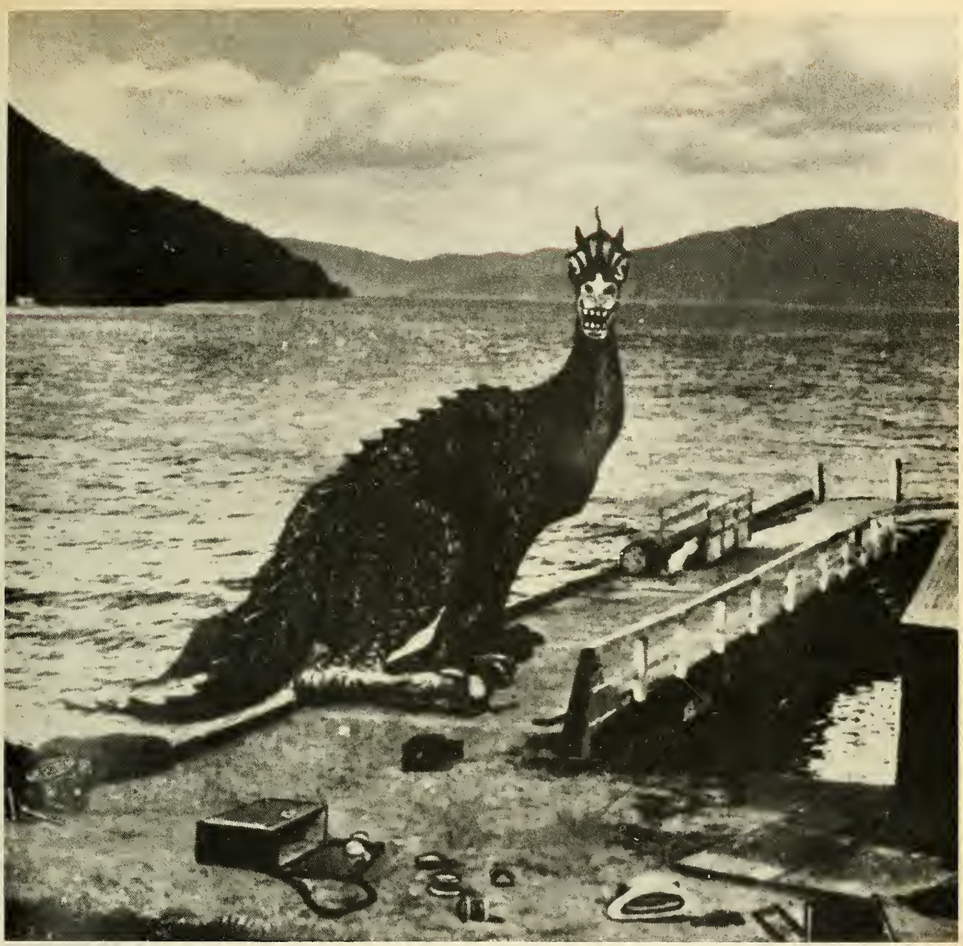
ON a recent trip to the north of Scotland I stopped off for a while at Inverness, which is the home port of the "Loch Ness monster." Inverness is as romantic and beautiful as only a Scotch city can be, with its castle and kirk and verdant hills. A swift-flowing stream carries the clear waters of the long, narrow Loch Ness northeastward to the Moray Firth. So I stood thoughtfully on the suspension bridge underneath which the Loch Ness monster must have passed if it came in from the North Sea. At that time the water was pretty low, but in time of flood a good-sized seal or even a killer whale might easily have passed up into the Loch in pursuit of salmon.

The latest "photographs" of the "monster" look like the dorsal fin of a killer whale.

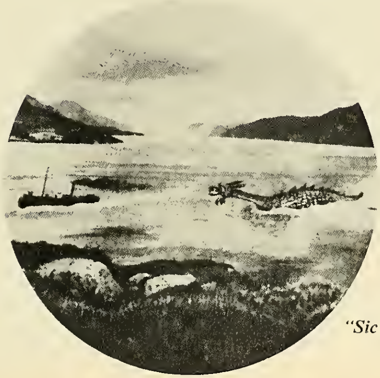
One hesitates to contradict twenty million Scotchmen, especially on their home grounds, but I noted for future use that *"Nessum monstrosum,"* as the animal has been facetiously named, must be a creature of protean form and varying proportions. In a guidebook to Loch Ness it is described and figured as an overgrown edition of the Japanese "giant salamander," which is a four-foot mud puppy with a head that has been flattened as if under the foot of a behemoth. Another veracious artist, however, represents the head as long and narrow, but with a giraffe-like tongue. Unfortunately, the lower jaw is not articulated at the posterior end. A third depicts the monster as emerging from the Loch and looking like a feeble libel on Charles R. Knight's well known restoration of *Allosaurus.* A fourth imaginative genius has produced a masterpiece by combining the features of several reptiles and mammals with the back fins of a teleost fish. But nothing but the *corpus delicti* satisfies the relentless scientist.

The fair city of Inverness teems with souvenirs of its beloved monster: postcards *ad lib.* in the Scotch equivalent of the "Five and Ten," little bronze monsters in the jewellers' shops, wooden monsters for the bairns to ride upon, and rubber monsters to take in bathing in the already chill waters of the Loch. And the silver tide of tourists still runs high. Surely the good beast is the greatest benefactor of his country since Sir Walter Scott. But why pick on Scotland for this innocent and profitable amusement? Many a country could show worse pastimes in the present period of world history.

*The Loch Ness monster has never been found and no one yet knows whether it is real or a hoax.*



*This obliging beast shows off his mammalian face and hind feet combined with reptilian scales and tail*



*"Sic 'em, Rover"*

# Celestial Events

by Thomas D. Nicholson

**Sun and Moon** The April sun moves out of the constellation Pisces into Aries on the 19th, and into Taurus in mid-May. Note that the sun was in Pisces when it passed the vernal equinox, even though that point along the sun's path also bears the name "First Point of Aries," reflecting the position of the vernal equinox 4,000 years ago.

The moon is just past full on April 1 (no fooling!), reaches last-quarter on the 8th, new on the 14th, first-quarter on the 21st, and full again on the 30th. Last-quarter occurs again on May 7, new moon on the 14th. Perigee moon (nearest the earth) is on April 14 and May 12, apogee (farthest from the earth) on April 26 and May 24. The perigee of April 14 will enhance the spring tide produced by the new moon some twenty-one hours later.

**Stars and Planets** If you haven't met Venus yet, do so at once while it still has some of its best nights ahead. Look into the west any clear evening after sundown, and the brilliant planet will be high in the sky, nearing its brightest in early May. It passes the Pleiades and Hyades (in Taurus) in early April, and the moon moves south of it on April 17 and 18 and May 16.

The sky around Leo, where Jupiter, Mars, and Saturn frolic near Regulus, is also worth getting to know early this month. After dark, Leo and the planets are in the east, opposite Venus, but they remain visible all night, disappearing in the west near dawn. The three planets reverse directions in April and May. Mars passes close to and above Regulus and Jupiter within less than a week in those months and Saturn in mid-June. Mars remains exceptionally close to Jupiter and Regulus throughout the two months, although dimming as it moves away from the earth, and the three are highlighted by the moon on April 23 and May 21. The moon covers Jupiter and Saturn (also the planet Mercury and the bright stars Regulus and Aldebaran) repeatedly in April and May, but the occultations will not be readily visible from the United States.

April 2: Mercury, at greatest westerly elongation, is a poor morning star.

April 5: Venus, at its greatest distance to the left (east) of the sun, is an excellent evening star. It will be spectacular for the next six weeks.

April 7: Mars ends its retrograde (westerly) movement, turns back east toward Regulus and Jupiter.

April 17–18: The moon is close to Aldebaran and Venus these nights.

April 21–22: The Lyrid meteors (15 per hour) reach maximum.

April 23–24: The moon passes Mars, Regulus, and Jupiter within four hours, after midnight.

April 25–26: The moon is very near Saturn tonight. Jupiter, ending its retrograde movement, turns around to move away from Regulus and toward Saturn.

April 27: Communities using daylight time shift clocks ahead.

April 29–May 4: Mars moves past Regulus on the 29th, Jupiter on the 4th. The Eta Aquarid shower (20 meteors per hour, but swift and often bright) reaches maximum on the 4th.

May 8: Venus is at greatest brilliancy in the evening sky.

May 13: Mercury, in superior conjunction, becomes an evening star.

May 15–16: The moon again passes close to Aldebaran and Venus (more distant). A daytime occultation of Aldebaran occurs over North America about 9:00 A.M., EST, on the 15th.

★Hold the Star Map so the compass direction you face is at the bottom; then match the stars in the lower half of the map with those in the sky near the horizon. The map is for 11:15 P.M. on April 1; 10:20 P.M. on April 15; 9:20 P.M. on April 30; and 8:25 P.M. on May 15; but it can also be used for an hour before and after those times.

# The Chandler Wobble

*Small aberrations in the motion of the earth's axis may be associated with other terrestrial phenomena*

When Galileo Galilei, speaking of the earth, is supposed to have said "and still it moves," he could not have imagined how complicated are the ways in which the planet does in fact move. He was convinced by the Copernican theory that we are in orbit around the sun. Maybe he realized that the slow motion of the equinox through the constellations is caused by a motion of the earth's axis relative to the stars. But our planet, tugged at by forces from its neighbors and flawed by its own imperfections, also moves in less obvious ways. It wobbles on its axis and pulsates with the tides; it slows down, then speeds up, only to slow down again. The study of these small internal motions of the planet is now called geodynamics, and it forms a major element in our national scientific research program.

Geodynamics was born in 1891 with the discovery that the earth's crust slips around with respect to the rotation axis. The North and South Poles move around the axis, so this is called the polar motion. The area covered by this wandering is only about thirty feet in diameter, barely the size of a motel swimming pool, but it may be related to large-scale earthquake activity, tectonic motions, variations in atmospheric circulation, and possibly to climatic changes. The first step toward understanding those speculative correlations, which, in turn, may provide a possible basis for predictive theories, is to find out by observation what the earth is actually doing. Until now, the earth has frustrated the theorists.

The linkages will seem less mysterious if we first know the background of the discovery of the polar motion. The story is of sociological as well as geodynamic interest because it pitted an untrained amateur scientist against contemporary scientific leaders, and the amateur won. He won because he didn't know enough to make the wrong assumptions.

Perhaps the first person to realize that a polar motion should exist was Leonhard Euler, the eighteenth-century Swiss mathematician who developed the theory of rotating bodies. Scientists already knew that the earth is not a sphere, but is slightly squashed at the poles. The distance from North to South Pole through the earth's center is about fifteen miles shorter than the diameter of the equator. Because of this, the earth spins like a child's off-center top. The top spins but if it is not vertical, the spin axis wobbles. This wobble is called a precession if it is very slow or a nutation if it is faster. The earth's spin axis precesses with a period of twenty-six thousand years, which we see as the motion of the equinox through the constellations of the zodiac. Euler predicted that, in addition, the axis should rotate with respect to the solid earth, by a very small and unpredictable amplitude, with a period of ten months.

We like to think of the earth as solid, as terra firma. The sheer solidity of the ground under our feet has been a comfort to untold generations of humans who have ventured onto the sea or into the sky. But solidity is an ambiguous idea. In high-school chemistry, we learn that a "solid" is something that "keeps its shape." Since our intuition of "shape" is largely formed by the abstract idealizations of Greek geometry, our understanding of solidity is often confused with the idea of "rigidity." In our intuitions, the lumpy spheroid that is our earth is transmuted into a sphere. To say that a sphere keeps its shape means that it is always a sphere—rigid, unchanging through the ages.

We know, of course, that this does not describe the real earth. On the most trivial of levels, the ocean tides ebb and flow twice a day. More seriously, a few years back, those living near San Fernando, California, saw the San Gabriel Mountains rise four feet within a few minutes. The view from California's Owens Valley provides spectacular evidence of crustal motions, with more than 3,000 feet of uplift in a single epoch. The earth is not rigid.

Still, one has difficulty imagining that its nonrigidity is very important. Aren't the tides just surface phenomena, involving only a little bit of water? Surely, even massive earthquakes move only small pieces of the earth. The force of intuition is so strong that scientists, too, are prone to think this way. For them, there is an even stronger incentive—the mathematics is much simpler for a rigid body.

Euler predicted that the axis of the "rigid earth" should move in a small circle around the geographic pole, with a period of ten months. This would cause the apparent latitude of all places on earth to change, also with a ten-month period. In principle, this circular movement would be found by measuring the positions of stars in the sky. The amplitude of the motion was too small to be found with the astronomical techniques of Euler's time, but in the nineteenth century Lord Kelvin, the British mathematician and physicist, revived the idea. Noting that telescopes were much improved, he urged observers and theorists to look for the latitude variations. A specific request in the late 1870s to the dean of American astronomy, Simon Newcomb, produced no more success than previous astronomers had had. The problem was that although everyone knew exactly what was being looked for—the amplitude of Euler's predicted ten-month variation in the earth's axis—no progress was possible because the prediction was wrong.

The first breakthrough came from a study totally unrelated to polar motion. A study of stellar aberration, that is, the apparent changes in star positions due to the finite speed of light, concluded that the observations were contaminated by a latitude variation in the

*In keeping with our standing as the "pioneer and a leader in the field of offbeat travel"* we offer adventurous travelers the first opportunity of exploring Western Australia in a small group, accompanied by Mr. Brian Kenny:*

The Last Frontier

OCTOBER 11 TO NOVEMBER 1, 1980

This tour, which has been three years in the planning and is designed for people who enjoy unique flora and fauna, includes visits to the vast karri and jarrah forests in the south, the subtropical Kimberley Range with its aboriginal cave paintings in the north, Broome and Rottnest with their magnificent beaches, and a three-day stay at remote Nyang Station Homestead where we participate in the ranch activities.

Accommodations are at the most luxurious hotel in Perth, a simple inn in the outback, and under canvas on an island in Lake Argyle and on the stark Abrolhos Islands.

*Detailed brochures of the tour are available from:*

site of the telescope. The period of the unknown effect was uncertain, but it was more like a year than ten months. It was left for an amateur astronomer and mathematician—in private life a prosperous New England merchant—to crack the puzzle. Seth C. Chandler probably didn't know enough theory to make the usual mistake. He announced in 1891 that Euler's variation was real, but the period was fourteen months instead of ten. This created a furor. As happens even in our day, the theorists were unwilling to believe an observation unless they knew a good theoretical reason for it. They were quick to claim that Chandler's analysis must be faulty or that his observations were bad. They could not imagine that Euler's theory was so wrong.

Nevertheless, the observations and the analysis withstood all attempts to bring them down. Finally, Newcomb found the answer—the earth is not rigid. Euler's theory was not wrong, it just didn't apply to the real earth. Chandler's result was the first observational evidence of the earth's flexibility, and Newcomb's qualitative explanation is still the simplest known.

The speed of a spinning body is controlled by its distribution of mass in such a way that—in the absence of friction—the spin energy remains constant. Every figure skater knows that spin varies and can be speeded up or slowed down as the arms are moved toward or away from the body. Newcomb reasoned that the same principle applies to the earth. If the earth were rigid, there would be no latitude movement, despite the enormous centripetal effects of the equator whirling around at 1,000 miles per hour. Because the earth is flexible, however, the centripetal "force" is not completely balanced by the internal strength until there is an elastic deformation, that is, an increase in the size of the equatorial bulge. This permits some of the mass to move outward. Not only does this slow the earth, like the skater, but it also slows the motion predicted by Euler. We know now that a flexible earth without oceans would show a polar motion with a period of approximately thirteen months. The sloshing around of the oceans lengthens this to fourteen months, Chandler's period. To distinguish this motion of the real, elastic earth from the theoretical motion, it is called the Chandler motion, or the Chandler wobble.

Actually, Newcomb's explanation only provided a cure for faulty intui-

tion; it does nothing to explain what really happens inside the earth to produce the Chandler wobble. We still don't know. Some theorists believe that there is convection in the earth's core; others are just as convinced that seismic activity drives the wobble.

It is difficult to imagine how convection could produce enough mass displacement to produce the observed polar motion, and this is not a very widely accepted theory. Many more experts consider that the seismic connection is more likely. We are beginning to realize that very massive earthquakes, especially those in tectonic subduction zones such as the fabled "ring of fire" of the Pacific Basin, involve much more displacement of mass than had been previously supposed. This displacement is a possible source of the wobble, equivalent to the motions of the ice-skater's arms. Some correlations between known earthquakes and observed polar motion have been claimed, but the evidence is not ironclad.

Chandler's discovery, once it was accepted as real, meant that theory was no guide to the behavior of the earth. Concerted and frequent observations were necessary to determine the true character of the Chandler wobble. It was still supposed, however, that the real wobble was just as simple as Euler's theoretical motion, so a short observing campaign should suffice. The International Latitude Service (ILS) was established in 1899 for that purpose, with five observatories spread around the world on the same circle of latitude.

Alas, reality is always more complicated than we imagine. The movement of the poles does not simply follow a neat circle with the Chandler period of fourteen months. The observed path looks rather like that of a drunken turtle on a racetrack, and the period is not a simple fourteen months. Certainly, the Chandler fourteen-month period is the most important movement, but there are also annual, semiannual, and random components. The "short" ILS operation is therefore being continued, nearly ninety years after its start, in a greatly expanded program called the International Polar Motion Service.

We now know that the total polar motion is produced by a combination of causes—the Chandler wobble and seasonal variations. Only the Chandler wobble, the fourteen-month part of the motion, is the result of shifts of interior mass, whatever their cause. The sea-

CRYSTALLINE GOLD
crafted by nature

Looking very much like modern sculpture, this rare specimen of crystalline gold was actually created deep inside the earth. It was formed when rising hydrothermal solutions were caught within a quartz cavity and underwent changes in temperature and pressure. Found in 1951 within one of Newmont Mining Corporation's California gold mines, the specimen is as remarkable for its survival in a working mine as for its rarity and beauty. In 1979, Newmont donated it to the American Museum of Natural History.

Since its formation in 1921, Newmont and the family of its founder, Colonel William Boyce Thompson, have donated several extraordinary mineral collections to the Museum.

Newmont Mining Corporation is one of the world's leaders in developing natural resources. Products include non-ferrous and precious metals, as well as other mineral resources such as oil, gas and coal.

sonal (annual and semiannual) changes in the earth's motion are the result of impulses imparted to the planet by large-scale atmospheric movements and other seasonal mass transport, such as snow accumulation and vegetation. Significant events of either kind should produce abrupt changes in the size of the wobble.

The cause of the Chandler wobble is still uncertain, but the seasonal variations in the speed and direction of the earth's rotation can be completely explained as effects of the weather.

Leaving its causes aside, does the polar motion have any effect of importance? Certainly, the original, practical interest arose because astronomers and navigators need to know where the earth is in space in order to interpret their observations correctly. More recently, meteorologists have raised a more intriguing idea about the polar motion. About forty years ago a Japanese scientist suggested that the Chandler wobble causes changes in the global climate. He and a few others have continued to investigate this, and the American meteorologist Reid A. Bryson believes that he has found a near-perfect correlation between the polar motion and abnormally heavy rainfall in a particular region of India. While there is no evidence that the correlation is other than accidental or that the degree of wetness in Poona has any connection with worldwide climate effects, still, a possible correlation remains an interesting idea for those who worry about world food supplies.

The Chandler wobble is so small and obscure that few of us are ever aware of it, yet, although the subject is controversial, a few specialists believe it might come to play an important role in the prediction of earthquakes and drought. All one has to do, it is presumed, is measure how the latitudes of places change. If only that were as easily done as said. One cannot observe the Chandler motion or the seasonal variations in polar motion. We can, however, observe the total polar motion. Decoding those observations to decide which part is Chandlerian, which part seasonal, and which part observational error is a ticklish business. At present, specialists do not even agree on whether there is only one Chandler period or two, separated by a few days. Most investigators assume that the annual effect of the atmosphere is of constant magnitude, but a former director of the U.S. Naval Observatory Time Service, one of our monitoring

agencies, now claims that even this is not true. The only way in which these problems can be resolved is through more accurate observations.

Nearly a century ago, a major concerted effort in geodynamics was begun with the founding of the International Latitude Service. Today, the space program and radioastronomy provide new ways to determine the polar motion with much higher accuracy. We don't yet know the details of the inside of the earth, but geodynamics provides the best promise for gaining more understanding. Astronomy began with the need to predict the seasons for planting and harvesting, related to the grossest motions of the earth. The need for disaster avoidance—navigational, seismic, and agricultural—is now spurring our quest for a deeper knowledge of the structure of our earth, through space-age observation of the tiny details of those motions.

*J. Derral Mulholland, who has advanced degrees in celestial mechanics and astronomy, is research scientist in the McDonald Observatory of the University of Texas at Austin.*

by Stephen Jay Gould

# Dr. Down's Syndrome

*The term he coined for trisomy-21 is defamatory, misleading, inaccurate, and dead wrong on all counts*

Meiosis represents one of the great triumphs of good engineering in biology. Unless eggs and sperm contain precisely half the genetic information of normal body cells, sexual reproduction cannot work. This halving, or "reduction division," occurs during meiosis when the chromosomes line up in pairs and pull apart, one member of each pair moving to each of the sex cells. The union of two halves by fertilization restores the full amount of genetic information, while the mixing of genes from two parents in each offspring also supplies the variability that Darwinian processes require. Our admiration for the precision of meiosis can only increase when we learn that cells of some ferns contain more than 600 pairs of chromosomes and that, in most cases, meiosis splits each pair without error.

Yet organic machines are no more infallible than their industrial counterparts. Errors in splitting often occur. On rare occasions, such errors are harbingers of new evolutionary directions. In most cases, they simply lead to misfortune for any offspring generated from such a defective egg or sperm.

In the most common of meiotic errors, called nondisjunction, the chromosomes fail to split. Both members of the pair go to one sex cell, while the other comes up one chromosome short. Offspring formed from the union of a normal sex cell with one containing an extra chromosome by nondisjunction will carry three copies of that chromosome in each cell, instead of two. This anomaly is called a trisomy.

In humans, the twenty-first chromosome suffers nondisjunction at a remarkably high frequency. About 1 in 600 to 1 in 1,000 newborn babies carry an extra twenty-first chromosome, a condition technically known as trisomy-21. These unfortunate children suffer mild to severe mental retardation and usually die at a young age (average life expectancy is about sixteen years). They exhibit, in addition, a suite of distinctive features, including short, broad hands; a narrow, high palate; rounded face and broad head; a small nose with a flattened bridge; and a thick and furrowed tongue.

The frequency of trisomy-21 rises sharply with increasing maternal age. We know very little about the causes of trisomy-21; indeed, its chromosomal basis was not discovered until 1959. We have no idea why it occurs so often and why other chromosomes are not nearly so subject to nondisjunction. We have no clue as to why an extra twenty-first chromosome should yield the highly specific set of abnormalities associated with trisomy-21. But at least it can be identified in utero by counting the chromosomes of fetal cells, thus providing an option for early abortion.

If this discussion strikes you as familiar, but lacking in one respect, I have indeed left something out. The common designation for trisomy-21 is Mongolian idiocy, Mongolism, or Down's syndrome. We have all seen children with Down's syndrome, and I feel certain that I have not been alone in wondering why the condition was ever designated Mongolian idiocy. Children with Down's syndrome can be recognized immediately, but (as my previous list demonstrates) their defining traits do not suggest anything Oriental.

Some, to be sure, have a small but perceptible epicanthic fold, the characteristic feature of an Oriental eye, and some have slightly yellowish skin. These minor and inconstant features led Dr. John Langdon Haydon Down to compare them with Orientals when he described the syndrome in 1866. But there is far more to the story of Down's designation than a few occasional, misleading, and superficial similarities; it embodies an interesting tale in the history of scientific racism.

Few people who use the term are aware that both words, Mongolian and idiot, had technical meanings for Down that were rooted in the prevailing cultural prejudice, not yet extinct, for ranking people on unilinear scales with the ranker's group on top. Idiot once referred to the lowest grade in a threefold classification of mental deficiency. Idiots could never master spoken language; imbeciles, a grade above, could learn to speak but not to write. The third level, the slightly "feeble-minded," engendered considerable terminological controversy.

In America, most clinicians adopted H.H. Goddard's term, "moron," from a Greek word meaning foolish. Moron is a technical term of this century, not an ancient designation, despite the length of metaphorical whiskers on those terrible, old moron jokes. Goddard, one of three major architects for the rigidly hereditarian interpretation of IQ tests, believed that his unilinear classification of mental worth could be simply extended above the level of morons to a natural ranking of human races and nationalities, with southern and eastern European immigrants on the bottom (still, on average, at moron grade), and established American WASPs on top. (Goddard instituted IQ tests for immigrants upon their arrival at Ellis Island. He proclaimed more than 80 percent of them feebleminded and urged their return.)

Down was medical superintendant of the Earlswood Asylum for Idiots in Surrey, England, when he published his "Observations on an ethnic classification of idiots" in the London Hospital Reports for 1866. In a mere three pages, he managed to describe Caucasian "idiots" that reminded him of African, Malay, American Indian, and

*Enter the world of Questers nature tours.*

When you travel with Questers, you have the advantage of our knowledge of the travel world. And our experience of the natural world. We are travel professionals. And our only tour program is Worldwide Nature Tours.

Under the leadership of an accompanying naturalist, we search out the plants and animals, birds and flowers... rain forests, mountains, and tundra... seashores, lakes, and swamps of the regions we explore. At the same time, we include the more usual attractions in touring—the cities, archaeological sites, and people.

The current Directory of Worldwide Nature Tours describes 29 tours varying from 9 to 36 days and going to virtually every part of the world. Included are The Amazon, Peru, Patagonia, Galapagos, Hawaii, Alaska, Death Valley, Everglades, Ladakh, Sri Lanka, Iceland, Scotland, Greece, Australia and New Zealand. Tour parties are small, the pace leisurely and itineraries unusual.

*Call or write Questers or see your Travel Agent today for your free copy of the Directory of Worldwide Nature Tours.*

Oriental peoples. Of these fanciful comparisons, only the "idiots who arrange themselves around the Mongolian type" survived in the literature as a technical designation. (I thank Dr. Carolyn Fluehr-Lobban of Rhode Island College for calling this story to my attention, sending me a copy of Down's obscure paper, and generally sharing her thoughts with me.)

Anyone who reads Down's paper without a knowledge of its theoretical context will greatly underestimate its pervasive and serious purpose. From our perspective, it represents a set of flaky, superficial, almost whimsical analogies presented by a prejudiced man. In his time, however, it embodied a deadly earnest attempt to construct a general, causal classification of mental deficiency based upon the best biological theory (and the pervasive racism) of the age.

Down played for stakes higher than the identification of some curious noncausal analogies. Of previous attempts to classify mental defect, he complained:

> Those who have given any attention to congenital mental lesions must have been frequently puzzled how to arrange, in any satisfactory way, the different classes of this defect which have come under their observation. Nor will the difficulty be lessened by an appeal to what has been written on the subject. The systems of classification are generally so vague and artificial, that, not only do they assist but feebly, in any mental arrangement of the phenomena which are presented, but they fail completely in exerting any practical influence on the subject.

In Down's day, the theory of recapitulation embodied a biologist's best guide for the organization of life into sequences of higher and lower forms. (Both the theory and "ladder approach" to classification that it encouraged are, or should be, defunct today. See my book *Ontogeny and Phylogeny*, Harvard University Press, 1977.) This theory, often expressed by the mouthful "ontogeny recapitulates phylogeny," held that higher animals, in their embryonic development, pass through a series of stages representing, in proper sequence, the adult forms of ancestral, lower creatures. Thus, the human embryo first develops gill slits, like a fish; later a three-chambered heart, like a reptile; still later a mammalian tail. Recapitulation provided a convenient focus for the pervasive racism of white scientists: they looked to the activities of their own children for comparison with normal, adult behavior in lower races.

As a working procedure, recapitulationists attempted to identify what Louis Agassiz had called the "threefold parallelism" of paleontology, comparative anatomy, and embryology—that is, actual ancestors in the fossil record, living representatives of primitive forms, and embryonic or youthful stages in the growth of higher animals. In the racist tradition for studying humans, the threefold parallel meant fossil ancestors (not yet discovered), "savages" (adult members of lower races), and white children.

But many recapitulationists advocated the addition of a fourth parallel—certain kinds of abnormal adults within superior races. They attributed many anomalies of form or behavior either to "throwbacks" or "arrests of development." Throwbacks, or atavisms, represent the spontaneous reappearance in adults of ancestral features that had disappeared in advanced lineages. For example, Cesare Lombroso, the founder of "criminal anthropology," believed that many lawbreakers acted by biological compulsion because a brutish past lived again in them. He sought to identify "born criminals" by "stigmata" of apish morphology—receding forehead, prominent chin, long arms.

Arrests of development represent the anomalous translation into adulthood of features that arise normally in fetal life but should be modified or replaced by something more advanced or complicated. Under the theory of recapitulation, these normal traits of fetal life are the adult stages of more primitive forms. If Caucasians suffer developmental arrest, they may be born at a lower stage of human life—that is, they may revert to the characteristic forms of lower races. We now have a fourfold parallel: human fossil, normal adult of lower races, white children, and unfortunate white adults afflicted with atavisms or arrests of development. It is in this context that Down had his flash of fallacious insight: some Caucasian idiots must represent arrests of development and owe their mental deficiency to a retention of traits and abilities that would be judged normal in adults of lower races.

Therefore, Down scrutinized his charges for features of lower races, just as, twenty years later, Lombroso would measure the bodies of criminals for signs of apish morphology. Seek,

# Take the new issue of

Saturday Review
THE COMEBACK OF DOWNTOWN
America Falls In Love With Its Cities–Again

# FREE!

## We'll send it to you to show you the new look and quality of Saturday Review.

To introduce you to today's forward-looking, brighter, livelier Saturday Review, we'll send you the next available issue free. That's the best way we know of introducing you to Saturday Review. And the best way for you to judge if this fast-growing new magazine —with a tradition that goes back more than half a century—is for you.

If you're interested in foreign policy, art, energy, cuisine, books, science, sports, movies, travel, music, education, business, TV, or humor, you will find Saturday Review the reading companion you've been looking for. A magazine that speaks your language . . . stimulates your thinking . . . adds to your enjoyment of the good things in life . . . and supplements your own wit and wisdom.

You will also find that Saturday Review brightens your mood. And your outlook on the future. We leave the gloom and doom to others. Our concern is with the possible, aspirations not desperation, improving the quality of all our lives.

We're reporting to our readers about the *comeback* of America's cities and their exciting futures—for residents, corporations, and tourists . . .

About the miracle of regeneration and the very real possibility that scientists may be able to regrow damaged human limbs—whole, perfect, and undiseased . . .

About practical, efficient and completely safe ways America may be able to produce all its own fuel—and free itself from dependence on Arab oil . . .

About the "reinvention" of television, which may turn the home screen into a combination of neighborhood movie house, computer center, penny arcade, and home mail-order catalog. Plus an electronic extension of the opera house, football stadium, town meeting, and hospital emergency room.

Saturday Review is fascinating reading today . . . and a bright window on tomorrow's world. It is a *quality* magazine . . . as concerned as you are with improving the quality of life in America and throughout the world. Day after day. Year after year.

Take this opportunity to get acquainted with the new Saturday Review. We'll send you the next available issue to read and evaluate, and enter a trial subscription in your name. If you like the issue, you can continue receiving copies by paying our invoice for *only $8* —covering a full year's subscription. *That's half the regular subscription price . . . the lowest rate available!*

And there is no risk. Because if you don't like your first issue, simply write "Cancel" on our bill and return it in the envelope we'll provide. The issue is yours to keep—free of course.

Take a moment now to send for your free issue. You have nothing to lose. And a world of new reading enjoyment to gain.

**Saturday Review**

P.O. Box 10007
Des Moines, Iowa 50348

## FREE ISSUE!

**Yes,** send me without cost the next available issue of Saturday Review. If I like it, I'll pay your bill for only $8 for a full year's subscription (24 issues). The regular subscription price is $16—I save a full 50%!

If I don't like the issue you send me, I'll simply write "Cancel" on your bill, return it, and that's the end of the matter. The issue is mine to keep free.

with enough conviction aforethought, and ye shall find. Down described his search with obvious excitement: he had, or so he thought, established a natural and causal classification of mental deficiency. "I have," he wrote, "for some time had my attention directed to the possibility of making a classification of the feeble-minded, by arranging them around various ethnic standards—in other words, framing a natural system." The more serious the deficiency, the more profound the arrest of development, the lower the race represented.

He found "several well-marked examples of the Ethiopian variety" and described their "prominent eyes," "pufffy lips," and "woolly hair . . . although not always black." They are, he wrote, "specimens of white negroes, although of European descent." Next he described other idiots "that arrange themselves around the Malay variety," and still others "who with shortened foreheads, prominent cheeks, deep-set eyes, and slightly apish nose" represent those people who "originally inhabited the American continent."

Finally, mounting the scale of races, he came to the rung below Caucasian, "the great Mongolian family." "A very large number of congenital idiots," he continued, "are typical Mongols. So marked is this, that when placed side by side, it is difficult to believe that the specimens compared are not children of the same parents." Down then proceeded to describe, with fair accuracy and little indication of Oriental features (beyond a "slight dirty yellowish tinge" to the skin), a boy afflicted with what we now recognize as trisomy-21, or Down's syndrome.

Down did not confine his description to supposed anatomical resemblances between Oriental people and "Mongolian idiots." He also pointed to the behavior of the afflicted children: "They have considerable power of imitation, even bordering on being mimics." Some familiarity with the literature of nineteenth-century racism is required to read between these lines. The sophistication and complexity of Oriental culture proved embarrassing to Caucasian racists, especially since the highest refinements of Chinese society had arisen when European culture still wallowed in barbarism. (As Benjamin Disraeli said, responding to an anti-Semitic taunt: "Yes, I am a Jew, and when the ancestors of the right honorable gentleman were brutal savages . . . mine were priests in the temple of Solomon.") Caucasians solved this dilemma by admitting the intellectual power of Orientals, but attributing it to their facility for imitative copying, rather than to innovative genius.

Down concluded his description of a child with trisomy-21 by attributing the condition to developmental arrest (due, Down thought, to the tubercular condition of his parents): "The boy's aspect is such that it is difficult to realize that he is the child of Europeans, but so frequently are these characters presented, that there can be no doubt that these ethnic features are the result of degeneration."

By the standards of his time, Down was something of a racial "liberal." He argued that all people had descended from the same stock and could be united into a single family, with gradation by status to be sure. He used his ethnic classification of idiots to combat the claim of some scientists that lower races represented separate acts of creation and could not "improve" toward whiteness. He wrote:

> If these great racial divisions are fixed and definite, how comes it that disease is able to break down the barrier, and to simulate so closely the features of the members of another division. I cannot but think that the observations which I have recorded, are indications that the differences in the races are not specific but variable. These examples of the result of degeneracy among mankind, appear to me to furnish some arguments in favor of the unity of the human species.

Down's general theory of mental deficiency enjoyed some popularity but never swept the field. Yet his name for one specific anomaly, Mongolian idiocy (sometimes softened to Mongolism) stuck long after most physicians forgot why Down had coined the term. Down's own son rejected his father's comparison of Orientals with children afflicted with trisomy-21, although he defended both the low status of Orientals and the general theory linking mental deficiency with evolutionary reversion:

> It would appear that the characteristics which at first sight strikingly suggest Mongolian features and build are accidental and superficial, being constantly associated, as they are, with other features which are in no way characteristic of that race, and if this is a case of reversion it must be reversion to a type even further back than the Mongol stock, from which some ethnologists believe all the various races of men have sprung.

Down's theory for trisomy-21 lost its rationale—even within Down's invalid racist system—when physicians detected it both in Orientals themselves and in races lower than Oriental by Down's classification. (One physician referred to "Mongol Mongolians" but that clumsy perseveration never took hold.) The condition could scarcely be due to degeneration if it represented the normal state of a higher race. We now know that a similar set of features occurs in some chimpanzees who carry an extra chromosome probably homologous with the twenty-first of humans.

With Down's theory disproved, what should become of his term? A few years ago, Sir Peter Medawar and a group of Oriental scientists persuaded several British publications to substitute Down's syndrome for Mongolian idiocy and Mongolism. I detect a similar trend in this country, although Mongolism is still commonly used. Some people may complain that efforts to change the name represent yet another misguided attempt by fuzzy-minded liberals to muck around with accepted usage by introducing social concerns into realms where they don't belong. Indeed, I do not believe in capricious alteration of established names. I suffer extreme discomfort every time I sing in Bach's *Saint Matthew Passion* and must, as an angry member of the Jewish crowd, shout out the passage that served for centuries as an "official" justification for anti-Semitism: Sein Blut komme über uns und unsere Kinder ("His blood be upon us and upon our children"). Yet, as he to whom the passage refers said in another context, I would not change "one jot or one tittle" of Bach's text.

But scientific names are not literary monuments. Mongolian idiocy is not only defamatory. It is misleading, inaccurate, and dead wrong on all counts. We no longer classify mental deficiency as a unilinear sequence. Children with Down's syndrome do not resemble Orientals to any great extent, if at all. And, most important, the name only has meaning in the context of Down's discredited theory of racial reversion as the cause of mental deficiency. If we must honor the good doctor, then let his name stand as a designation for trisomy-21—Down's syndrome.

# "I wanted to design a camera that takes photographs no other camera can."

Maitani

Such was the challenge that Maitani, the celebrated Olympus camera designer, set for himself.

If he had listened to conventional wisdom, he would have folded up his drawing board and gone home promptly at five.

Instead, Maitani persisted. And created the Olympus OM-2.

The fully automatic Olympus OM-2 is the only camera that measures the light *during* exposure.

Because two sensors read the light that reflects off the film surface the instant the shutter opens.

So the shutter may stay open for up to two minutes as the camera adjusts for changes in light and automatically closes at the precise moment perfect exposure has been achieved. No other camera can do it.

The OM-2 also embodies all that Olympus SLRs are justly famous for. It's a light, compact, rugged camera with a bright viewfinder and well-proportioned controls.

And that's just the beginning. You can snap on a five-frame-per-second motor drive, or a winder, or a 1,000mm lens, or any of 300 plus components from the stellar Olympus OM system.

The Olympus OM-2 is what happens when a brilliant designer sets his sights on the impossible.

To create what's possibly the world's ultimate camera.

For information write Olympus, Woodbury, N.Y. 11797.

## Aura of Feathers

*by Phyllis Rabineau*

Feathers have provided a medium for artists in all parts of the globe over thousands of years. Some featherwork, regarded as wealth because of its beauty, fragility, and scarcity, is associated with high social status. Other objects embody the symbolic connection of feathers and birds with spiritual powers.

An intricate relationship between wealth, status, and spiritual belief is known from traditional Hawaiian culture, where feather costuming was among the most valued possessions of aristocratic chiefs. The feathers were taken from tiny birds, members of several species of honey creeper. They were gathered by professional hunters, who trapped the birds, plucked them, and attempted to release them unharmed. Often only a few feathers were taken from each bird, and their consequent scarcity added to their value. Areas of the islands where these birds lived paid their state taxes in the form of feathers.

The plumage was not merely wealth, however; it was believed to be highly charged with spiritual power, or *mana,* and handling it subjected people to potentially dangerous interactions with this power. Only individuals who themselves had great *mana,* men of high social status, could safely work in feather arts. This work had to be accompanied by religious observances, and the designs on completed pieces were believed to result from spiritual inspirations. High-ranking women could clean and sort feathers and make their own feather necklaces or headbands, called leis. But only aristocratic men could fashion the most valuable objects, such as helmets, cloaks, and shoulder capes.

---

**Feather Arts: Beauty, Wealth, and Spirit from Five Continents,** an exhibit of more than 250 feather artifacts, will be on display at the American Museum of Natural History from April 18 through August 31.

---

There are several reasons feathers seem charged with spiritual symbolism, but certainly the most important is the special ability of birds—flight. To mankind, bound to the earth and to the everyday concerns of life, flight is a dream motif, a poetic metaphor. In visions, men fly to the heavens, visiting spirits who can use their powers to assure good harvests, cure illness, foretell the future, and vanquish enemies. Flight can also represent a joyous freedom of the soul.

The deeply religious Huichol Indians of Mexico view feathers as prayers for life and decorate many objects with them, especially costuming used on the sacred peyote quest. The Huichol believe that because birds can fly, they know all that happens in this world and the world of the spirits. Their plumes share this power and can convey it to the shaman, a ritual specialist who uses feathers to locate and draw out the source of illness in his patient's body.

The delicacy, fragility, and lightness of feathers are also important symbolic qualities. For example, ancient Egyptians believed that after death the soul was judged by weighing its heart on a balance scale against the feather of truth. If the heart was pure, it would balance; a heart heavier than the feather was burdened with sin and would condemn the soul to hell. Down is especially significant in many North American Indian ceremonies as a manifestation of great spiritual power. A headman's dance from the Pacific Northwest Coast is performed wearing a headdress loosely piled with eagle down. Released by the movements of the dance, the down floats throughout the audience, symbolizing the blessings and spiritual strength of the headman. The fragile substance serves to express the most potent of forces.

In many cultures, feather headdresses may serve as material manifestations of spiritual energy. Many

peoples believe that the head is the center of this energy and ascribe special power to the hair. For example, the highland people of New Guinea, in a belief reminiscent of the Old Testament story of Samson, see a man's hair as the locus of his strength. The ghosts of his ancestors live in his hair, and a luxuriant coiffure is evidence of their support. To enhance this strength, the men augment their own hair with wigs, combs, and other ornaments. In Brazil, the shamans of a group called the Tapirapé used a red feather headdress to draw into themselves the spiritual forces of lightning and thunder in a dramatic ceremony during which they struggled to overcome the destructive power of these elements.

Often, the mere form of a headdress suggests spiritual energy radiating from the head, in the manner of halos so well known in Christian and Buddhist iconography. With their shimmering colors and symbolic attributes, feathers are ideally suited for representing this aura.

The behavior of specific birds has also figured in the symbolism of feather arts, and in this respect no bird has been more important than the eagle. Many peoples have used the eagle to symbolize the ideals and accomplishments of their culture and have reserved its feathers for special uses. This symbolism was especially strong among native North Americans for whom the eagle represented both secular and sacred power and often the intermingling of both.

While Plains bonnets are easily the best-known headdresses from North America, many other kinds were made. Some groups used eagle feathers; others chose feathers from different birds of prey, especially owls, which were admired for their stealthy, nocturnal hunting and their frequent association with the powers of sorcery. Another North American bird associated with magic was the jay, with its reputation for mischief and stealing from other birds' nests.

Folk sayings from highland New Guinea compare men to bowerbirds, a family with distinctive mating habits: the male bowerbird builds a complex structure, consisting of a dance platform and viewing area, connected by a gallery of upright stems. Upon the first platform, he performs a courtship dance while the female bird watches from the nearby viewing area. In a similar fashion, the New Guinea men prepare special dance areas in their villages, and bedeck themselves in finery—much of it feathered—to dance in hopes of dazzling and delighting the watching women.

These men say that the physical beauty displayed in their dances is linked with both economic and spiritual factors. The feathers and other decorations are a form of wealth and, therefore, marks of material success both for the individual wearing them and for the kinsmen from whom he has borrowed some of the ornaments. Furthermore, a good appearance is likely to have the magical power to help a man increase his available supply of ornaments and other objects of wealth, and also acquire more wives, who are regarded as a special form of wealth.

Finally, a beautiful appearance is impossible without the assistance of ancestral spirits, who help a man hunt birds for decorative plumage and also help make the plumage look bright. To assure these ancestral blessings, the men observe various religious customs. If these rituals are carried out properly, the spirits will congregate in a man's hair and help him achieve his goals.

*Phyllis Rabineau, custodian of collections in the Department of Anthropology of Chicago's Field Museum of Natural History, is curator of the traveling exhibit* Feather Arts.

# Czar Alexander's favorite rocks

During the month of January, visitors to the American Museum of Natural History may have noticed truckloads of unidentified wooden crates being unloaded at the 77th Street entrance. Inside the crates, nestled in cotton, wadded newspapers, and cloth, were some 40,000 mineral specimens—the largest mineral acquisition the Museum has ever made.

The Museum bought the collection, one of the world's largest, from Columbia University for $500,000, thereby increasing its own collection by 80 percent. The purchase "puts our collection on the map," according to George Harlow, assistant curator of Mineral Sciences. "Big collections like this," Harlow says, "don't come up for sale anymore—they've been gobbled up."

Negotiations for the transaction began last year. According to Wallace Broecker, chairman of Columbia's Department of Geology (which in the last few decades had shifted its research emphasis from mineralogy to other areas of geology), the university felt that a museum would be better able to care for the collection.

Most of the Columbia minerals were acquired in the late nineteenth and early twentieth centuries when many big mines were just being opened. "Today," says Harlow, "you couldn't get some of these minerals at any price—their localities have been cleaned out. The real strength of this collection is its remarkable diversity. There are Russian pieces from the czar; South American, French, African, Canadian pieces—it's all there."

The new acquisition will complement the Museum's present minerals, which were gathered more with an eye to the beauty of the stones than as a systematic collection. The Museum, for example, possesses about 2,500 cut gemstones, including the Star of India, which are beautiful but of lesser interest to scientists than an assemblage of drab clay ores from Africa.

The Columbia collection had been assembled by generations of professorial rockhounds, such as Thomas Egleston, who brought back thousands of specimens from the western United States in the 1850s and 1860s. In 1869, Czar Alexander II traded some of his prized minerals for specimens from Columbia. The university received a two-pound platinum nugget, a cluster of large, deep green emerald crystals flecked with mica, and assorted beryls and topazes. Columbia retained the platinum nugget, but the American Museum now has the rest.

The collection also includes rare uranium ores collected by Prof. Paul Kerr in the 1940s and 1950s, when the first commercial uranium mines were being opened up. Kerr recalls collecting at the Schinkolobwe uranium mine in the Belgian Congo (Zaire) during the early days of World War II. "The green ore piled on the ground," he says, "looked like alfalfa fields. There was a galaxy of rare and unknown uranium minerals. Those ore piles would have made any mineral collector go crazy." From one stockpile destined for the ore crusher, he saved a two-foot-long specimen of moss green torbernite and specimens of jet black uraninite and pitchblende.

Other collectors brought back rubies from Burma, stibnites from Japan, a Kelly smithsonite from New Mexico, and a "peerless" cluster of acanthite crystals from Freiberg, East Germany. During the excavations for the New York City subway system, Columbia collectors dogged the footsteps of the engineers and collected, among other specimens, some beautiful garnet crystals and a rare apophylite with white crystals.

Some of the minerals will replace similar ones in the Museum's Hall of Minerals and Gems, but it will be years before they are put on display. Harlow estimates that it will take at least three years to catalog the collection even if the department buys a computer to aid in the task. When the new quarters of the Department of Mineral Sciences were being built in 1979, the curators allocated space for a large storage area to avoid the warehousing headaches so many other Museum departments were facing. Nevertheless, the size of the Columbia collection will cause storage problems. "We built twenty years of expansion into our new storage area," says Harlow, "but this just about fills it up."

*Douglas J. Preston*

### Masked Dance-Drama

On tour for the first time in the United States, the *Royal Dancers and Musicians from the Kingdom of Bhutan* will perform at the American Museum of Natural History on Sunday, April 27, at 3:00 P.M. in the Auditorium. Wearing intricate masks, dancers will enact scenes from traditional Buddhist legend and Bhutanese folklore. Tickets are $9 for the general public, $5 for members. For information, write the Membership Office.

### Discovery Tours

In January 1981, C. Bruce Hunter, author of several books on ancient Mexican ruins, will lead an archeology tour of the Mixtec and Zapotec sites of Oaxaca, Mexico, and other pre-Columbian areas. Tour participants will also visit the ancient cities of Teotihuacán, Cholula, and Xochicalco. For more information write to Discovery Tours at the Museum.

### Lopsided Brains

The evolution of the brain will be the topic of the fiftieth annual James Arthur Lecture. Norman Geschwind will present *Anatomical Asymmetry of the Brain in Humans and Animals: An Evolutionary Perspective* on Monday, April 7, at 6:30 P.M. in the Auditorium. The lecture is free and open to the general public.

### Tahitian Voyage

In 1976, Ben Finney sailed a reconstruction of an ancient, double-hulled Polynesian canoe from Hawaii to Tahiti—a distance of 3,000 miles. Finney will recount his experience on Wednesday, April 16, at 7:30 P.M. in the Auditorium. He will show slides and films of his voyage and discuss some controversial theories of ancient human migrations. *Hokule'a: The Way to Tahiti* is free to members, $3.00 for nonmembers.

### Alvin Ailey

The *Alvin Ailey Repertory Ensemble* will give a free performance at the Museum on Wednesday, April 23, at 7:30 P.M. in the Auditorium. Tickets will be distributed at the first floor Information Desk starting at 5:15 P.M.

### Films of India

Films by Satyajit Ray and Jean Renoir will be among those shown in the Auditorium on two Saturdays, April 5 and 12, from 1:00 to 4:30 P.M. This free program will feature the lives, religions, and crafts of the peoples of India.

### The Graduates

The Class of 1980 of the High School of Performing Arts will present a free afternoon of dance on Sunday, April 20, at 2:00 P.M. in the Auditorium.

### Golden Opportunity

*It's Gold*, a special exhibition in the Roosevelt Rotunda, will remain open until April 18. Ralph J.T. Bauer of the Museum's Department of Exhibition has been commended for his ingenious design of the free-standing exhibition in which more than a million dollars' worth of gold is displayed.

# Documenting People and Places on Film

*"Odyssey," a twelve-week television series on anthropology and archeology. Executive producer Michael Ambrosino. To be shown nationally on the Public Broadcasting Service (PBS), beginning Sunday evening, April 6, at 8:00 P.M., EST (check newspapers for local time).*

Over the past decade there has been growing interest, both professional and popular, in the development of "visual anthropology." While the surge of popular interest may be relatively new, it should be pointed out that various forms of visual anthropology have been around for some time.

One hardly needs to be reminded that Margaret Mead's use of film dates back to her collaboration with Gregory Bateson in Bali in the mid-1930s. Franz Boas, who was influential in bringing so many innovations into the mainstream of American anthropology, was also an early experimenter with the uses of photography and film for anthropological fieldwork and archival research. And one must not forget the remarkable work of another pioneer , Edward Curtis, whose many paintings, drawings, photographs, and films of North American Indians represent a treasure-trove of visual anthropology.

Interestingly enough, both Boas and Curtis, working separately, perhaps even in professional rivalry with each other, happened to shoot quite a bit of film footage of the same Indian tribe, the Kwakiutl of the Pacific Northwest. Their respective ways of using film—revealing very different attitudes toward the medium, the tribal peoples, and the audiences for whom the films were intended—are among the many fascinating issues explored by a provocative new film on the life and work of Franz Boas, the man often called the father of American anthropology. Entitled *Franz Boas (1858–1942)*, the film is one of the highlights of the new television series "Odyssey." This series was put together by executive producer Michael Ambrosino, who also created the highly acclaimed science series "NOVA."

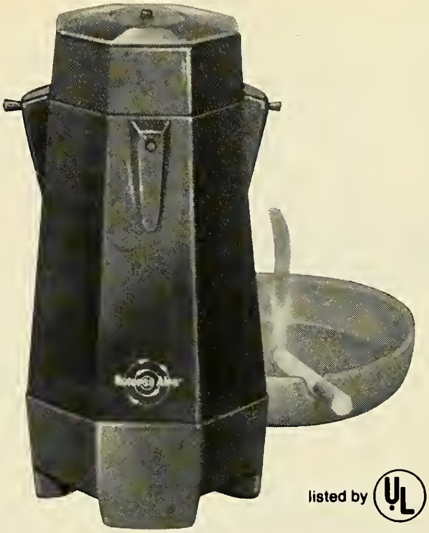
In "Odyssey" the focus is on anthropology and archeology, and while these two disciplines are closely related, they do not seem to be equally suited for treatment in the film and television media. Having previewed most of the series, I have to report a split verdict, with the programs on archeology being downright dull at times (the program entitled *Other People's Garbage*, for example, is utterly devoid of interest, except briefly in the section on excavating slave quarters on a South Carolina cotton plantation). On the other hand, the six programs devoted to anthropology display a rich variety of filmic approaches to a rich variety of subject matters and are consistently excellent.

Fortunately, the superior quality of the anthropology half of "Odyssey" more than makes up for the deficiencies of the archeology side. With the exception of the film portrait of Boas, the anthropology programs consist of ethnographic film studies that explore various tribal cultures from around the world. Of the five ethnographic films,

# Now! A Scientific Way to "SCRUB" the Air Clean!

## Clear The Air with "NATURES-AIRE"

### Makes dust, odor and pollutants vanish—leaves the air country fresh



listed by UL

**Discover nature's own "secret" for fresh air...**
Ever notice how wonderfully fresh and clean the air is after a good thunderstorm? Well, it wasn't the rain that cleansed the air... it was the negative ions generated by the storm. Now you bring that same natural phenomenon into your home, office or car with Natures-Aire, the ion generator that works like Mother Nature to cleanse, purify and refresh the air you breathe!

**Natures-Aire—a controlled "thunderstorm"**
That's right! Natures-Aire safely and electronically emits negative ions to create the same beneficial balance of ions found in the great outdoors—right in your home. You just plug it in and it silently and immediately begins to sweep unpleasant odors, smoke and pollutants from the air—leaves it refreshed and smelling sweet and country-fresh.

**Unlike many similar products**
Natures-Aire produces precisely the right balance of ions—25,000/cm3. Scientific research has shown that much more or less would not have the beneficial effect. In fact, Natures-Aire is now the *standard by which Underwriters Laboratories measures other negative ion generators*. It is the first ion generator to receive U.L. listing.

**Negative Ions—Nature's "Good Guys"**
Though you can't see them working, negative ions actually grab on to particles of dust, smoke, organic and inorganic pollutants and sweep them from the air. Just as negative ions cleanse the air after a thunderstorm, Natures-Aire cleanses the air in your home with its gentle, controlled stream of negative ions—Nature's "good guys".

**Natures-Aire—no matter where you live**
Studies show that winds carry harmful pollutants everywhere—even to tucked-away communities. That's why Natures-Aire is so vital for everyone. In the near future, negative ion generators will undoubtedly be standard equipment in airplanes, office and apartment buildings. But you don't have to wait! You can start protecting your whole family from harmful pollutants and unwanted odors right now with Natures-Aire.

**Perfect when you entertain**
You'll love breathing purified air everyday, but imagine what a great benefit Natures-Aire will be when you have parties. No lingering cooking odors to embarrass you—no smoke filled rooms when the guests are gone! Yes, Natures-Aire will actually destroy stubborn odors, smoke, dust and other harmful pollutants in the air—not just cover then up with an artificial "freshener." Lets the whole family breathe easier! Just think what an important difference it will make to your personal environment.

**Proven safe and effective**
Yes, Natures-Aire's graphite conductive fibers are so safe a baby could chew on them. And Natures-Aire sweeps any airborn micron-size pollutants from the air and deposits them in the wall or floor. *So effective at eliminating smoke and odors, you'll notice the pleasant difference in just minutes!*

**Now—Mountain-Aire for your Car, Van, Truck or Boat**
Natures-Aire has a "twin" that works wonders in your car, too. It's called Mountain-Aire. You just plug it into the cigarette lighter of your car and enjoy a smoke-free, odor-free, pollutant-free freshness wherever you go!

**Put your nose to the test without risk!**
You're probably a little skeptical. That's okay—we're so convinced that Natures-Aire and Mountain-Aire are the most effective, revolutionary air purifiers around that we're prepared to offer you a 30-Day Money-Back Guarantee. Prove it to yourself. Use Natures-Aire in your kitchen, bathroom, living room, bedroom (many say they actually sleep better!) and Mountain-Aire in your car and see for yourself if you don't notice the refreshing difference right away.

**Small price—big reward!**
You can own the product of the future for just $79.95. What a small price to pay for clean, invigorating air for years to come! But remember—if you're not absolutely convinced that Natures-Aire and Mountain-Aire far out-perform other air purifying systems, simply return your order for a prompt, courteous refund.

**Pure air... Pure value!**
Imagine! For fresh, pure air every day of your life—you pay just $79.95. *A small investment when it comes to protecting the well-being of your whole family!*

**Safe enough for a baby**... yet effective enough to rid your home of lingering smoke, odors and pollutants. Leaves it wonderfully refreshed and sweet smelling!

Our team of botanical and wildlife experts has compiled a programme of tours that is both exciting and imaginative.

**BOTANY & WILDLIFE 1980**

**China** — the first botanical tours to China staying in Peking, Chengtu, Mt. Omei, Kunming and Hong Kong. Departures on May 4; May 18 and October 5 for 22 days.

**Kashmir** — flower hunting in beautiful mountain country with easy pony-riding or walking, botany excursions and three idyllic days in houseboats at Srinagar. Leaving June 21 for 23 days with a stop-over in Delhi.

**Papua New Guinea** — the plant and bird life with several days at the Bensbach Wildlife Lodge, the Baiyer River Lodge and the Wau Ecology Lodge. Leaving on August 9 for 26 days with a stop-over in Singapore.

**Australia** — the flora of tropical Queensland, visiting the Girraween and Lamington National Parks, the Atherton Tablelands and the Lake Barrine National Park. Leaves September 8 for 23 days stopping in Singapore and Sydney.

Experts escorting the tours include Kenneth Beckett, Anthony Huxley, Roy Lancaster and Bryan Sage. Details of these and other tours from our USA representatives:

three were originally produced in Great Britain by Granada Television for a British series called "Disappearing World."

Broadcast on British television in the mid-1970s, the "Disappearing World" impressed both professional circles of anthropologists and filmmakers and the general television audience. There was an immediacy and an authenticity in these films that enabled professional and popular audiences alike to come away feeling that they had not only learned something about other cultures but that they had also learned from the *inside*, as it were, by getting close to the everyday lives of individuals.

This, indeed, was the goal of Brian Moser, who created the series. Moser wanted as much authenticity as possible; he wanted to avoid the glib superficiality or outright falsification that can occur when a globe-trotting film crew flies in, shoots from the hip, and flies out a few days later. Moser conceived of each film as a collaborative effort in which anthropologists and filmmakers would work together as equals and share in the overall conception of the films. Moreover, each project was planned to allow the anthropologist-filmmaker team sufficient time *in the field* to shoot their film over many months of day-to-day interaction with the tribal peoples.

The high quality of the finished films in the series demonstrates the wisdom of Moser's approach (although the title "Disappearing World" was a most unfortunate choice, full of rather dubious ideological connotations, and one that several anthropologists refused to be associated with). But most importantly, the overall success of the series proved that visual anthropology can be good anthropology and, at the same time, good entertainment of a high artistic and intellectual order.

Although Michael Ambrosino's current "Odyssey" series for American public television is hardly as innovative—or as successful on the whole—as "Disappearing World," it does offer, among other things, three of the most interesting films from the British series. The first of these to be shown (May 11) is *Ongka's Big Moka*, a joint creation of producer-director Charlie Nairn and anthropologist Andrew Strathern. It is a fascinating study of the efforts of a "big-man," or man of authority, in the New Guinea highlands to organize his relatives and tribesmen in a large, complex political alliance system, the formation of which depends on, and is publicly sealed by, the giving of a huge gift, or *moka*, comprised of pigs, ornamental shells and feathers, cash, and various other forms of wealth.

To be shown later in the series are *Masai Women* (May 25) and *The Sakuddei* (June 22). One of the most highly acclaimed of the earlier British series, *Masai Women* is a product of the collaboration of producer-director

*Children in* N!ai, the Story of a !Kung Woman, *a film about the Bushmen of the Kalahari*

ADVERTISEMENT

### *You don't know me, I realize . . .*

# But, I want you to have this before it's too late.

Hello . . . My name is Bud Weckesser. I'm 46 years old and I own a small company in Dunkirk, New York. Our phone number is 716-366-8300.

A number of years ago I lived in an apartment in Kent, Ohio. I had no savings and a beat-up old station wagon that still wasn't paid for.

One night my wife and I were playing cards with some friends. Mary mentioned casually that—on our budget—she was sure she knew 101 ways to fix hamburger. That hurt. So I challenged her. "If you'll type up the recipes," I said, "I'll take out a small ad in the National Enquirer and we'll see if anyone will pay $3.98 for your collection of recipes."

I rented a P.O. Box in Kent and placed a small ad. It was surprisingly cheap.

Several weeks later I stopped by the post office. I walked over to my box. When I looked through the little glass window on the door, I almost dropped my key. The box was stuffed—jammed —full of letters. All of them contained checks for $3.98—and they'd come from all parts of the U.S. and Canada.

The next few days were hectic, to say the least. My wife typed the recipes. I had them duplicated, stapled them together and our crude little book was born. But, every day, orders continued to pour in. And every day we'd bank the money and send out our stapled recipe booklet.

I decided to try another ad. This time I placed a classified ad for some of my beer and wine making recipes in Popular Mechanics. Again, the orders poured in. Over $1,000.00 in just several weeks. And, as our business grew, I corresponded with other people . . .

- A husband-wife team from Santa Barbara put together a booklet about how to "win at card games." It pulled $14,870.00 in just 5 months . . . all cash orders . . . all from a small ad . . . all by mail.
- An Oregon man informed me he had made over $14,000.00 selling his small booklet about getting rid of moles and gophers in your yard. Again . . . all by mail.
- A Maryland man wrote an 8½" × 11" booklet of business advice. So far it's brought him over $140,000.00 . . . all by mail.

Don't misunderstand. This isn't a get-rich-quick scheme. It's a business, and, as such, it's speculative. But test ads are cheap (as low as $13.50 for a national ad) and the profit potential is staggering! An Ohio man I spoke with put a large display ad in a national Sunday supplement. A few days later the orders started pouring in—mail sacks full of cash! Within the next two months he received over $220,000.00 in CASH orders for his $3.00 booklet.

Perhaps you're saying to yourself, "Yes, but this only works for a few lucky people." If that's your thought—and I don't blame you for being skeptical— please try this simple little test. It won't cost you a cent.

1. Go to the library and get some year-old issues of magazines with classified ads—like Popular Mechanics and Sports Afield, etc.
2. Select current issues of the same magazines.
3. Compare the classified ads. Look at the current issue then at the back issue. Note how many of the same classified ads are still running, ONE YEAR LATER. People don't continue running ads for over a year unless they're making money at it.

Let me give you some more amazing facts about this unique little business:

★ You can start at home . . . in your spare time . . . quietly . . . it won't interfere with your present job.

★ You can take out a test ad for as little as $13.50 in a variety of well-known national magazines.

★ You don't even have to write a booklet yourself. I'll show you how to obtain "how-to" booklets at wholesale prices—or below. They're already written, already printed and ready to sell. Even better, you don't have to buy them until you've tested your ad and have the cash orders in hand. In short, you don't tie up any money in stock or supplies of books.

★ You can set your own hours. All you need is a post office nearby.

★ You can deduct up to 33% of the expenses on your home if you set up your office at home.

★ You can travel whenever you wish—or just loaf much of the time. All you need to do is pick up your mail twice a week—or have someone do it for you. You'll open orders, remove the checks (95% of them don't bounce, believe it or not) and bank your receipts.

★ In the afternoon or evening, you can type the labels for the small envelopes you'll use to ship your booklets. Drop them off at the post office and you're done. No bosses, no layoffs, no strikes, no rat race.

I've put all of my instructions—every secret—in a simple Starter Guide. And if you're wondering why I'd share my business with you—especially if it's so profitable—here's why:

The range of topics and ads is almost infinite. I won't be competing with you nor you with me. I've got a whole drawer full of ideas I haven't even tried yet. There's plenty of room for everyone.

I'll show you—

- How and where to get national ads for only $13.50 . . . ads you can run month after month.
- How to obtain FREE ADS—YOU PAY ONLY IF THE AD IS SUCCESSFUL.
- How to start with no money in books or supplies.
- Where to obtain hundreds of pre-printed booklets—at super low wholesale prices.
- How to word your ad—I'll include various sample ads.
- How to set up your office in a spare room or basement.
- I'll also include a giant list of "how-to" topics.
- Plus . . . all the sample ads, forms, lists, addresses, and details you'll need to get started within only 10 days.

If you're still skeptical, let me offer you a most unusual guarantee. I'll send you my Starter Guide to inspect. Keep it for one year. That gives you plenty of time to actually try my materials. If, at the end of one year—or anytime in between—you want your money back, just return what I've sent you. I'll issue you a full refund **within three working days**—no nonsense, no delays. That's our iron-clad guarantee.

Also, please feel free to POSTDATE your check THIRTY days. If you're not satisfied with my materials just send them back within 30 days and I'll return your original UNCASHED CHECK.

To begin, just write the words, **Dollars In Your Mailbox** on a piece of paper. Enclose your check or money order for $12.95 and send it to me, Bud Weckesser, at my address: Green Tree Press, Dept. 127 , 10577 Temple Road, Dunkirk, N.Y. 14048, If you wish First Class Air delivery, please add $1.00.

Or, you may charge it to your Master-Charge or VISA card—be sure to include your account number and expiration date.

For EXTRA FAST SERVICE, call us at 716-366-8300 and give us the credit card information over the phone. You'll receive my materials for one year at absolutely no risk to you. That's our unconditional guarantee.

Christopher Curling and anthropologist Melissa Llewelyn-Davies. Through a combination of voice-over commentary, direct interviews with tribal women, and several scenes of vivid interaction among the Masai themselves (with English subtitles of the Masai dialogue), this film provides a sensitive insight into how these women feel about their roles in a society where all prestige and property are the exclusive domain of the males.

Also included are two ethnographic films that are not from the British series—*Cree Hunters of the Mistassini*, a Canadian production that follows the Cree Indians as they fly north in winter to spend several months on their traditional hunting, trapping, and fishing territory (to be shown June 8); and the long-awaited release by John Marshall of a new film on the Bushmen of the Kalahari (which will be seen April 13). Marshall compiled this new film, called *N!ai, the Story of a !Kung Woman,* out of footage that spans three decades and was shot in the course of seven major expeditions by the Marshall family to study the !Kung Bushman tribe.

An ethnographic film with a thirty-year time span is absolutely unprecedented. The picture of social change that emerges from *N!ai* should shake up some of the dominant notions in anthropology, especially that of "the ethnographic present," a euphemism that all too often functions as an excuse to avoid the present entirely, to eliminate or ignore any signs of social change over time in favor of narrow-minded concentration on whatever can be found—or "reconstructed"—of the old, "traditional" culture.

An extreme and touchingly naïve example of this romantic, nostalgia-oriented approach to anthropology is provided by the revealing photograph of Franz Boas at work in Ted Timreck's marvelous film-portrait, *Franz Boas (1858–1942)*, to be shown April 20. The photograph shows Boas setting up a scene in which his Kwakiutl Indian subjects, in traditional garb, are ostensibly demonstrating a particular aspect of their traditional culture. But this photograph reveals that Boas is holding up a huge curtain to block the modern picket fence and painted two-story frame house that stands just behind his staged scene of "traditional" Kwakiutl culture.

Indeed, one of the many issues explored insightfully in this rich,

multilevel film on Boas's life and work is precisely the question of *how* anthropologists collect, use, and conceptualize the visual data they obtain. Ted Timreck has found film footage of Kwakiutl dances that were staged and shot by Boas, who then cut the footage up into individual frames, marked them, and handed them over to an artist whose task it was to make drawings and maquettes for later use in preparing dioramas. And Timreck has also found, and included in *Franz Boas,* some wonderful photographs of Boas modeling various traditional Kwakiutl hunting, dancing, and ceremonial gear. Such photographs ultimately tell us more about Boas the man, Boas the actor, Boas and his extreme identification with the tribal peoples he studies, than they tell us about the Kwakiutl.

But that is all part of the picture, if I may play with words here, of how anthropologists work with visual data. The important thing to keep in mind—and something that separates anthropology from archeology—is that in anthropology there is significant work being carried out in the visual media—film, video, and still photography. In the case of ethnographic film, for example, we who watch the film can share in the excitement and discovery that accompany actual fieldwork in progress, fieldwork being carried out in the very film we are watching.

In archeology, on the other hand, apart from aerial photography or underwater filming (one "Odyssey" program shows the recovery of material from a sixteenth-century Spanish armada warship that sank off the coast of Scotland), little work is carried out through film, video, or photography. These visual media may indeed be used to document work that was originally done by other means, but what we then get—and the "Odyssey" programs on archeology give us more proof of this than we need or want—are illustrated lectures. And these illustrated lectures are particularly deadly when, as in *The Chaco Legacy* (June 1), they are slickly spiced with endless panning shots of picturesque ruins at sunset, and with celestial choirs providing metaphysical mood music on the soundtrack.

*James Roy MacBean teaches film at Rutgers University, where he is coordinating efforts to establish a research institute in film studies. A noted critic, MacBean is the author of* Film and Revolution.

NEVER BEFORE — has pure gold been added to perhaps the most beautiful of all United States silver coins — *the Walking Liberty* half dollar.

Our bi-tone process by which 24 Karat gold is applied to coins *with extreme precision,* creates a magnificent two tone of precious metals. This miraculous process was invented by Jimmy Chin and these unique silver and gold coins are available only through Cartwheels, Inc. of Wilmington, Delaware.

The coins are authentic and *not* newly minted medals. Lenscote II, our exclusive coin cover, permanently seals the two tone beauty. The necklace comes with a 14 Karat Gold filled chain (24" for her or 27" for him.) The complete necklace is $129

*You will receive a numbered Certificate of Authenticity with each piece and all are gift wrapped in velvet boxes. We guarantee a full refund if not delighted.*

*The Franklin Mint Record Society presents*
*the ultimate private library of recorded music*

# The 100 Greatest Recordings of all time

A unique collection of the greatest performances ever recorded,
selected by an international panel of music authorities
and presented on 100 records of superb proof quality.

For the first time in history, the world's greatest works of music —*and* the greatest recorded performances of those works—have been brought together in one unique collection of distinctively high-quality records. Truly the ultimate collection of fine recorded music.

These are the supreme masterpieces of man's musical genius, performed by the most outstanding artists of the century. Together, they form a record library unprecedented—and unsurpassed—in the entire history of music. *The 100 Greatest Recordings of All Time.*

### The greatest music—and the greatest performances

An international panel of renowned music authorities was appointed to participate in the selection of these great recordings. This distinguished panel considered countless recordings of each of the greatest works of music—a momentous task.

For instance, members of the panel reviewed 24 recordings of Beethoven's 7th Symphony and chose the *one* recording they considered superior to all others: Toscanini with the New York Philharmonic.

From 30 great recordings of Tchaikovsky's Nutcracker Suite, the panel selected the *one* greatest performance: Arthur Fiedler and the Boston Pops.

Similarly, the recordings of other great symphonies, concertos, sonatas, rhapsodies, ballet and vocal music were reviewed and the most outstanding performance in each instance recommended.

The creation of this definitive collection has been made possible through the cooperation of leading record companies both here and abroad. And now, *The 100 Greatest Recordings of All Time* is being issued by The Franklin Mint Record Society.

Among the works chosen for this collection are immortal masterpieces by Beethoven, Brahms, Mozart, Tchaikovsky, Schubert, Rachmaninoff, Debussy, Verdi—performed by such superb artists as Vladimir Horowitz, Jascha Heifetz, Enrico Caruso, Van Cliburn, Isaac Stern, Artur Rubinstein, Leontyne Price —with the world's great orchestras under the direction of Toscanini, Ormandy, Bernstein, Stokowski, von Karajan, among others.

In every sense, the ultimate private library of recorded music—to be cherished for a lifetime, and presented as a legacy to later generations.

### Superb proof-quality records

Each record is exceptional for its clarity and tonal quality—capturing the beauty of today's finest performances *and* of the historic performances of the past. Indeed, the recordings of legendary greats such as Caruso and Ponselle have been remarkably *improved* by electronically removing imperfections in the earlier recordings.

A superior vinyl material, containing its own anti-static element, is used in the production of these records. This special material, and the process by which the pressing is made, results in a record that is more rigid, durable and resistant to dust. A record that has true fidelity, clearer sound quality and a long life.

To further assure their quality, the records are pressed in a special "clean room" similar to the facility in which The Franklin Mint produces its flawless proof-quality coins. In this atmosphere-controlled clean room, the most meticulous attention is paid to the pressing of the records. And the records are carefully inspected to make certain that the full quality of each original recording is faithfully preserved.

Together, these important features enable the Society to create a collection of *proof-quality* records—records that offer greater clarity of sound, and are quieter and clearer.

### Handsome library cases provided

To house these magnificent proof-quality records, special library cases are provided for all 100 records in the complete collection. Each library case holds two long-playing 12" records and is sturdily hardbound and attractively designed. Displayed in a bookshelf, breakfront or cabinet, these handsome library cases will be an impressive addition to any home.

The fifty library cases also include specially written and illustrated commentaries discussing the great masterpieces and their composers, and providing fascinating background information on the famous orchestras, conductors and soloists included in the collection.

Thus, you will enrich your understanding of great music—and you will introduce your entire family to a world of pleasure and cultural satisfaction.

### Created solely for subscribers to this series

*The 100 Greatest Recordings of All Time* are produced *exclusively* for those who enter subscriptions to this series. The collection may be acquired *only* from The Franklin Mint Record Society. It will not be sold in any record stores.

To begin building your private library of the world's greatest performances on *proof-quality* records, mail your application by May 31, 1980.

GUARANTEED PRICE: In spite of strong inflationary pressures in the record industry, the price of $10.75 per record will be *guaranteed* to each subscriber by The Franklin Mint Record Society for *every* record in the collection.

# Morel Victory

*Nostalgia as well as mushrooms is the object of the Boyne Hunt*

Photographs by Adelaide de Menil

### by Raymond Sokolov

When Gerald Ford was president, certain Washington wags predicted that he would fire the White House chef and bring in someone from his hometown of Grand Rapids who knew how to cook the cuisine of Michigan. Not particularly a fan of Ford, I was nonetheless stung to hear the food of my natal region so scurrilously dismissed as a gastronomic nullity. True, Michigan could boast no local dishes worth matching against Louisiana gumbos or Key lime pie, but we had raw materials second to none: Lake Superior whitefish and Traverse City cherries. Come to think of it, Michigan was also the best place in the country to find a delicacy that even the White House chef, a Frenchman whom Mr. Ford wisely did not dismiss, would have been delighted to present to the most discriminating international guests. Morels.

Morels are generally conceded to be the most delicious of all mushrooms. But they are hard to find in most areas and fruit for only a few short days in the spring, usually in May. Also, no one has ever succeeded in cultivating morels. The true gourmet will never pass up an opportunity to eat their distinctively pitted, furrowed caps.

On my most recent trip to France, which took place providentially in May, the giant asparagus was in season, but I needed no special encouragement to opt, at the legendary Restaurant de la Pyramide in Vienne, for a first course of morels and cream in puff pastry. The *patronne* must have employed a small army of people to scour the woods for all the morels she served that Sunday. Morels camouflage themselves brilliantly in leaves and underbrush. Stands of oak, tulip poplar, and old elms, abandoned apple orchards and burned-over fields are all likely places to look, but no set of conditions is guaranteed to produce morels, and they often pop up singly rather than in bevies. At least they do seem to grow in the same places year after year.

Once, taken to proven morel sites in Rockland County, New York, I came away with four pounds, a gift from the forest worth, to me, its weight in caviar. And so I felt confident that I could hold my own with the mycophiles who assemble each May at Boyne City, Michigan, for the National Mushroom Hunting Championship.

That the woods around Boyne City were full of morels was obvious even to the casual motorist driving north from Detroit. At the Sugar Bowl Restaurant in Gaylord, the jumping-off place for the northern Lower Peninsula, morels were a "special" on the menu. We were only a few miles from Boyne City now, and farmers' mailboxes had mushroom signs on them to show they had morels for sale. At other times of the year, residents of this hilly, wooded region might vaunt its ski slopes or its lakes or remind you that Ernest Hemingway came here as a boy on vacation from Oak Park, Illinois, and later wrote about the area in his Nick Adams stories. But in mid-May, the morel is king in the Boyne Valley.

In Boyne City itself, on the morning of the first day of the two-day championship, a banner over the main street welcomed contestants. The marquee of the Boyne River Inn said: "Have a Mushroom Burger." Nearly every store window had been painted over with mushroom scenes, and children had worked botanically accurate morels into brightly colored cartoons featuring Big Bird, the Cookie Monster, and Snoopy. One precocious youngster executed a faintly risqué window painting and captioned it: "Boyne City has Wild-n-Crazy Morals."

The hoopla didn't stop there. At the registration area manned by the Boyne Valley Lions and the Chamber of Commerce, there were mushroom T-shirts and stationery for sale. A small carnival midway was opening as contestants from all over the country lined up at 7:00 A.M. to get their official numbers and paper collecting bags. Then there was a motor parade of con-

testants through the town and on out to the secret hunting grounds.

Some 200 cars snaked their way to a remote road that ran past farms up to the edge of a woods. Here, we all piled out and waited for the starting signal. Most of the contestants were outsiders. Only about twenty-five people were local, and they had to compete in a separate division because they knew the territory too well. Dana Shaler, a young millwright from nearby Advance, had won twice before in the local division. The rest of us were mainly first-timers.

"I would say 90 percent of the people come to say they've been in a national event," said Bud Bates, one of the organizers of the contest. He was quick to point out that participants have come from as far as Hawaii and Alaska. But, he added, most come from Ohio and Michigan. And when you stop to talk to the contestants, it is clear that they have more on their minds than the tinny luster of winning a hokey national contest.

Homer Syfert, 77, who worked in the Detroit Post Office for thirty years before retiring, has been coming to the Boyne hunt for the past ten years. He has made it to the finals nearly every year but has never won. His interest in mushrooms goes back to his boyhood on a farm south of Decatur, Illinois. "I once picked eleven bushels," he said. "My father told me which ones to pick. You have to look on hills facing south. In Illinois, there were more woods then. All our neighbors ate mushrooms."

Paul Whipple also grew up on a farm—in Michigan—and learned how easy and safe it was to pick morels. Today, he works as a painting contractor in Muskegon, Michigan, but during the season he drives north more than a hundred miles and spends three days foraging for mushrooms that he will parcook, freeze, and eat for the rest of the year. For Whipple, and many other entrants in the National Mushroom Championship, the contest is in large part just an excuse to relive their youthful involvement with mush-

rooms. Poised and ready to charge into the Michigan woods, they are hoping to win some public acclaim for a vestigial skill learned as part of an agricultural, postfrontier Midwestern upbringing.

To the outsider, who had always thought of morels as part of a sophisticated European culinary world, it was a surprise to discover that this American heartland tradition of mushrooming centered almost exclusively on the elusive members of the morel genus, *Morchella*. But as with most folk traditions this one has a pragmatic logic behind it.

Midwestern woods, like all woods, teem with hundreds of mushroom varieties, many of which are toxic or inedible. Morels, however, are delicious and safe, virtually foolproof. Because they fruit so early in the season, there are almost no other mushrooms around to confuse them with. And morels don't even look like classic mushrooms. They have neither gills nor pores. Their cone-shaped caps are pitted or ridged. Once you have seen one, or even a picture, you can never mix them up with anything else, except possibly the false morels, which have wrinkles, not pits or ridges. Also, the cap of the true morel is attached directly to the stalk, whereas the head of the false morel is attached only at the top and hangs down over the stalk like a skirt. It is the case that one true morel, *Morchella semilibera*, is only partially attached, but the exterior of its cap is ridged in the same way as other true morels. In any event, a look at the photographs in a mushroom field manual will make positive and safe identifications a simple matter, as simple as they were for farm folk in Michigan and Illinois earlier in the century.

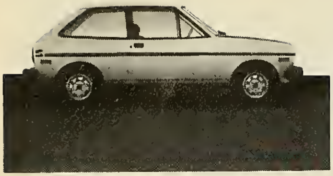
When Homer Syfert was growing up, his family and their neighbors were too cautious to attempt foraging for other kinds of mushrooms that required more sophisticated knowledge. They had the sense to know the limits of their mycological information, so that what they didn't know didn't hurt them. They were certain, however, that *Morchella* looked different from "ordinary" mushrooms even if they didn't realize that it belonged to a special class of fungi, called ascomycetes, whose spores are produced in a microscopic saclike cell called an ascus. (Most of the mushrooms in the woods are basidiomycetes, fungi whose spores are found on spinelike projections, or basidia, on the outside of a club-shaped cell.)

The Syferts and the Whipples did know, however, that true morels are hollow and should be sliced in half lengthwise, examined for insect infestation, and then thoroughly rinsed to remove sand or dirt. They did not have to be reminded not to use plastic collecting bags—plastic causes morels to wilt almost immediately—because there weren't any in those days. But they did master the simple technology of morel preservation.

Drying is probably still the best way, and you can do it most easily in a fruit and vegetable dehydrator. Barring that, spread the morels out in an oven set at the lowest temperature, with the door open, and leave them there until they are crisp. Store in jars in a cool dark place. Reconstitute by soaking one cup of mushrooms in two cups of hot water for thirty minutes. You can also sauté morels in butter until all moisture has boiled away and then freeze them with decent results.

This kind of morel lore was easy to come by as one waited for the contest to begin. Morel hunters are basically generous with information. But once the actual competition began, once we had all run uphill into the woods, it was every man and woman for himself and herself.

Ninety minutes later, breathless from the chase, I returned to the starting line with a slim but still precious bag of fifteen morels. Others had hundreds. I didn't survive the cut and had to sit out the finals the next day, when Paul Whipple won the outsiders' title



**Ford Fiesta and the option that could pay for itself.**

**Two award winning choices.**

**Just ask your Ford Dealer.**

When you order your new Ford Fiesta, be sure to consider the one option that could pay for itself. Ford Motor Company's Extended Service Plan. It's available to help protect you against rising service costs. And it's backed by Ford Motor Company and honored by participating Ford Dealers nationwide.

To learn more about what this plan covers and what it costs, see your Ford Dealer.

**The option that could pay for itself.**

Ford EXTENDED SERVICE PLAN

with 309 mushrooms and Dana Shaler copped the local division championship with 445.

That is a lot of morels, but contest veterans were quick to remind us that the highest total in previous years was well over 900, and that the largest single mushroom ever found in the state—10½ inches tall and weighing 14 ounces—would have dwarfed any mushroom picked that day.

Even so I was impressed with the superior skills of the winners, impressed until I stopped on the way south at a farm with a roadside mushroom sign. A little girl led me into a garage filled with bushels of morels. She had collected them after school and on weekends, just as generations of Midwesterners have done before her. "I know where to look," she explained nonchalantly. For her and a few other farm children in the Boyne Valley, the National Mushroom Festival was irrelevant. In their world, what matters is that the woods are still able to produce their bounty—and their parents have shown them where to look for it.

**Morel Soufflé**

(Adapted from *Morel Mushroom Cookbook*, by Betty Ivanovich, R-B Food Products, 7626 Auburn Road, Utica, Michigan 48087)

½ pound morels, chopped
4 tablespoons butter, approximately
Heavy cream
3 tablespoons flour
Salt
Pepper
4 egg yolks
5 egg whites, beaten until stiff but not dry
Bread crumbs

1. Sauté the chopped morels in 3 tablespoons of the butter for 5 minutes. Meanwhile, butter the inside of a soufflé dish and set aside. Preheat oven to 375 degrees.
2. Remove mushrooms from pan with a slotted spoon, draining juice thoroughly back into pan. Reserve mushrooms.
3. Measure the cooking liquid in the sauté pan. Add enough heavy cream to make ¼ cup liquid. Pour this mixture back into the pan. Add the flour. Heat, stirring constantly, until the mixture reaches the boil. It should be smooth and thick.
4. Remove flour mixture from heat. Stir in salt and pepper to taste and continue stirring until cool.
5. Add mushrooms to cooled mixture. Stir in egg yolks, one at a time, mixing until well incorporated.
6. Fold in egg whites and pour soufflé batter into buttered soufflé dish. Sprinkle lightly with bread crumbs. Dot with butter. Bake for 30 to 35 minutes, or until the top springs back when touched lightly.

Yield: 3–4 servings

# Ford Fiesta. It received a seven-flag salute.

## The car that wowed Europe is winning the hearts of America.

Ford Fiesta. The little front wheel drive car that comes from Germany. Applauded all over Europe by the experts for its engineering, design and overall performance. It was voted the most significant import of the year in 1978 by readers of Car and Driver. And when you understand how beautifully Fiesta performs, you'll understand why it continues to get rave notices.

Germany 1976
Car that Makes the Best Sense—*Mot*

Finland 1976
Car of the Year
—*Tuulilasi*

## Front wheel drive.

Through rain, ice, sleet, hail and snow, Fiesta's remarkable front wheel drive traction will help you keep your appointed rounds. And its Michelin steel-belted radials will help you come to grips with all kinds of roads.

Denmark 1976
Car of the Year
—*Morgen Posten*

Italy 1977
Most Successful Foreign Car—*Motor*

## True German efficiency.

Americans love Fiesta's manners. It prefers sipping to guzzling. Just consider these EPA mileage figures.

**26** EPA EST. MPG

**38** HWY. EST. MPG

Now compare these estimates to other German imports. Actual mileage may differ depending on speed, weather and trip length. California estimates will be lower. Actual highway mileage will probably be lower.

Yugoslavia 1977
Car of the Year
—*Automotive Writers*

## A masterpiece of European engineering.

Fiesta is assembled by Ford in Germany. And its European engineering makes it feel right at home on streets and highways of America. It's quick, nimble and maneuverable.

Ford Fiesta is sold and serviced by over 5,000 authorized Ford Dealers across America. There's even an Extended Service Plan available, providing longer protection over your car's basic warranty. So test-drive a Fiesta today. You'll discover why it's won international acclaim.

**Keith Kennedy**, left, was invited to Mackinac Island in 1977 to look into an outbreak of *Lecanium* scale, a fruit tree pest. He soon realized that he had "stumbled onto a 'textbook' example" of how a chemical used against one pest (in this case flies) can indirectly cause an outbreak of another pest. An assistant professor of entomology at Michigan State University, Kennedy now devotes his research to scale outbreaks in urban environments, several of which have occurred in Michigan because of fly- and mosquito-spraying programs.

Uncovering the solution to the Mackinac Island insect problems, according to coauthor **Richard W. Merritt**, required not only study but also the consumption of "mass quantities of Mackinac Island fudge," one of the resort's claims to fame. Merritt, an associate professor of entomology at Michigan State, is primarily interested in aquatic and semiaquatic insects of streams and flood plains, although the dung-breeding flies of Mackinac Island were well within his experience. His graduate work was an ecological study of the insects associated with cattle droppings.

**Don Moll** grew up along the banks of the Illinois River in Peoria, Illinois. He spent much of his boyhood fishing, swimming, and collecting "critters" in the river. Along the way, he developed a strong interest in the ecological changes that brought the river from its former pristine condition to its present polluted state. An assistant professor of ecology and vertebrate zoology at Southwest Missouri State University, Moll's fascination with turtles led him to combine his two interests in a study of how the river's turtles have fared through a century of change. Fieldwork on turtles runs in the family. Moll's brother, Edward, published an article on Malaysian turtles, "Drummers Along the Perak," in the May 1978 issue of *Natural History.*

# FORD'S EXCLUSIVE CLUB ROOM

**1980 Ford Captain's Club Wagon. Best EPA gas mileage rating of any van. Station wagon luxury—much more room.**

Here's one exclusive Club everyone can easily enter! Ford's advanced Club design means more move-around room for driver and plenty of inside passenger comfort. Built tough: Separate body-on-frame construction, rugged Twin-I-Beam suspension. See your Ford Dealer. And ask about Ford's Extended Service Plan.

**BEST VAN GAS MILEAGE**

**18** EPA EST.* **26** Hwy. EST.*

Built Ford Tough

*300 Six, optional 4-spd. manual transmission. Compare these estimates with others. Your mileage may differ, depending on speed, distance and weather. Actual highway mileage will probably be less than estimated. California estimates lower.

**Welcome inside the Club.** Ford's Captain's Club Wagon comes with fold-out snack/game table, four recline/swivel chairs, and seat/bed.

**Combination seat/bed.** Folding rear seat turns Ford's Captain's Club Wagon into a mini camper.

**Super wagon size, too!** Ford wagons offer seating plans for four to 15 passengers. And Ford Club Wagons offer light- and heavy-duty Trailer Towing Package options.

## A Plethora of Pox Viruses

Five years ago in "The Dubious Gamble Against Smallpox" (August/September 1975) Pascal J. Imperato took a somewhat skeptical look at the efforts to eradicate smallpox. This month (to the delight of Imperato and everyone else), the World Health Assembly is due to announce formally that smallpox has been eradicated from the earth. The news has been out unofficially since last fall, when the last strongholds of smallpox in Africa were confirmed to have been free of the disease for two years.

Imperato wrote about the logistical difficulties of tracking down every last case of smallpox (he directed a smallpox eradication program in west Africa for six years), and he also discussed some of the questions about the nature of the disease that have continued to interest researchers.

Could there be an animal reservoir of smallpox, he asked, from which the virus might reemerge to infect human beings? Might any of the various animal pox viruses turn out to be variants of smallpox that could be transformed into smallpox itself (variola)? The latter question became particularly pointed when Russian scientist S.S. Marennikova reported in 1978 and 1979 that starting with a monkeypox mother strain and growing it on a chick embryo membrane or in hamsters, she was able to come up with something indistinguishable from smallpox. It was already known that monkeypox on rare occasions infects human beings, although it seldom spreads from one person to another.

Now, Frank Fenner, of the Australian National University and chairman of the WHO's Global Commission for Certification of Smallpox Eradication, says that the evidence has accumulated to the point where it is clear that Marennikova's virus could not have come from monkeypox. Other investigators have failed to duplicate her work, and genetic mapping of the pox viruses has shown that monkeypox and smallpox are, in effect, stable, distinct species. One cannot be transformed into the other by one or even several mutations.

As to whether smallpox can maintain itself in animal populations, there is strong evidence against this possibility. Donald A. Henderson, dean of the School of Hygiene and Public Health of Johns Hopkins University, and formerly in charge of WHO's efforts against smallpox, points out that there has never been an outbreak of the disease that was not traced to human sources. If there were animal reservoirs, untraceable outbreaks would be expected. And, of course, there have been no new eruptions of smallpox in the past two years.

On the other hand there are the confusing reports of the discovery of "whitepox" in animals. Six such incidents have occurred, four reported by Marennikova. Whitepox is a puzzle; it is indistinguishable from smallpox in laboratory tests. Dr. James Nakano of the Center for Disease Control in Atlanta, head of the WHO Collaborating Center for Smallpox and Other Pox Virus Infections, says we "really don't know" what whitepox is or where it comes from. Henderson points out, however, that "in each instance in which whitepox was isolated, work was proceeding in the same laboratory with smallpox. Thus, it is impossible to state with certainty that these whitepox isolates do not represent contaminants."

Imperato, now chairman of the Department of Preventive Medicine and Community Health at Downstate Medical Center in Brooklyn, New

"Get the jump on action pictures. With Minolta's Continuous Automatic Exposure System."
-Bruce Jenner, Olympic Decathlon Winner.
74

If you can see it happening, you can take a picture of it with the dependable Minolta XG-1.

Because the XG-1 measures light in a way that makes action photography just about foolproof.

Even if your subject is moving from sunlight to shadow, Minolta's Continuous Automatic Exposure System changes the exposure for you. Automatically.

That means after you focus, the compact, lightweight XG-1 does all the work. And you take all the credit.

As for value, the reliable XG-1 is the least expensive automatic 35mm SLR Minolta has ever made.

Add to your range of creative ideas by adding a Minolta Auto Winder, Auto Electroflash, or any of the more than 40 computer designed Minolta lenses.

For more information about the Minolta XG-1, write Minolta Corporation, 101 Williams Drive, Ramsey, N.J. 07446. In Canada: Minolta, Ontario, L4W 1A4. Or see your photo dealer. He'll show you why the Minolta XG-1 is the camera that lets you take the pictures you never thought you could take.

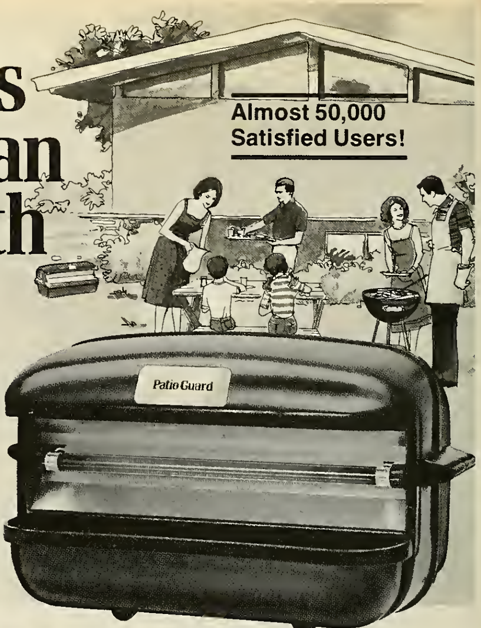
The automatic choice for action photography.

# Clear Mosquitoes From a Third of an Acre* or More With Patio Guard™

## Developed by the U.S. Department of Agriculture, perfected by Pestolite,™ it actually draws up to 300 different insects away from where you stay!



**Almost 50,000 Satisfied Users!**

Patio Guard takes the best time of day away from the insects and gives it to you and your family to enjoy. It makes outdoor living and entertaining bug-free, buzz-free and bite-free!

### A Lure Like A Magnet

The government developed it. A lure like a magnet. Irresistible to mosquitoes, moths, gnats, wasps and beetles. About 300 annoying flying insects in all.

This development, by the U.S. Dept. of Agriculture at its field laboratory in Beltsville, Md., was as timely as it was extraordinary. Because we also learned about the dangers of D.D.T. just about then.

Naturally, this government research was public property. But there were problems that remained to be solved. What the U.S.D.A. had shown, beyond doubt, was the fact that light sensitive, phototropic, insects would always respond to a particular kind of ultraviolet light. More, that the lure of the light extended far beyond the supposed ability of these insects to see. At the very minimum, insects were attracted by the light over as large an area as 1/3rd of an acre—14,250 square feet!

### Foolproof, Safe, Silent

The light attracted. But it didn't kill the insects. This is where Pestolite stepped in and created a simple, totally foolproof, completely safe and silent way to get rid of every bug attracted to the light, killing without chemicals, without polluting the environment, or without electrocution.

Patio Guard can't harm your children or your pets. It only kills bugs. And so effectively it's approved by the Environmental Protection Agency, recognized by the Food & Drug Administration as well as the USDA for use where food is packaged, in hospitals and commercial kitchens.

### Low, Low, Cost

Pestolite's achievement is notable in other extremely important ways. The other companies that used this discovery came up with bug killers that are no more effective; in fact, ignore the peskiest ones and electrocute the other insects with a popping sizzling sound. And their units sell for $125.00 and $150.00 more.!

### Mosquitoes Come Out As the Sun Goes Down

So, with Patio Guard you get the best as well as the least expensive model by far. In the late afternoon or early evening you'll be able to relax in the shade, linger over your barbecue, stay by the pool, play tennis while it's cool—without being bothered by mosquitoes. Even after it rains you can forget about sprays, throw away those smelly citronella candles.

And you'll be able to stay outside as late as you like. Imagine watching TV, playing cards, sitting and talking, even reading or relaxing in a hammock as you enjoy the evening breeze. Yes, for the first time ever, you can spend summer evenings outside instead of cooped up in an air conditioned room or hiding behind screened doors and windows.

### Operating Procedure

Patio Guard mounts in minutes, virtually anywhere. On a tree, any kind of fence, the side of your house, even a brick wall. Set it up about 25 feet from where you generally stay. Fifty feet may be even better. Then plug it in. Ordinary house current is all that's needed, though you may have to use an extension cord. The operating cost is less than 30 cents a month.

The ultraviolet light, with the exact frequency for maximum effectiveness, is produced by a unique, fluorescent-type bulb constructed of special glass and housed in scintillating reflectors. Often called "black light" because it's invisible to the human eye, it seems to compel the insects to come ever closer. Actually capturing them because they can't—or won't—fly away.

Just why it works no one knows. Not the scientists who developed it, not the entomologists who tested and confirmed the phenomena. They do suspect, however, that the light's effectiveness is somehow connected with the constant early evening and night time propagation (sex) activity of these insects.

### The End Of Them

Captured, unable to escape or fly away, the mosquitoes, moths, gnats and other insects are caught in a down-draft (created by a small electric fan) and plunged into the water in the pan below where they're drowned. All you do is change the water about once a week, emptying the tray in the bushes where the birds eat all the bugs. It's a clean, simple, seconds-a-week procedure.

You can have the Patio Guard not for $199.95 or $160.00, but for just **$49.95,** plus $3.95 shipping and handling.

Moreover, because you can't get the Patio Guard in any store, we'll send it to you to try without risk or obligation for 15 days. It does what the government says, what we promise, or return it to us for a complete refund.

Credit card holders may call the toll free number above. Or send your check made out to Dimensions Unlimited to the address below. (Illinois residents include 5% sales tax.)

Designed to stand up to all kinds of weather, to provide years of trouble-free service, Patio Guard is covered by an unconditional one-year warranty. The special UV bulb will be replaced free if it fails for any reason—except negligent damage—within 6 months.

Order your Patio Guard today. It is a bargain at the price, but the pleasure of bug-free, bite-free summers around the house is priceless.

York, reports that he is encouraged by the lack of untraceable outbreaks of smallpox and by the lack of good evidence for animal reservoirs, but says that some viral diseases spend long periods of time in animal populations before reemerging and that more time in a smallpox-free world is needed to lay to rest definitively the possibility of an animal reservoir of the disease.

## Electricity in Lampreys

Salamanders have the enviable ability to regenerate amputated limbs. In "Skin Batteries and Limb Regeneration," October 1977, Richard Borgens wrote that the source of this electrifying skill was, indeed, electricity.

The salamander's skin, it seems, is a kind of battery; in transporting positive sodium ions into the body, it generates an electric current. When Borgens changed the makeup of the water salamanders lived in or used chemicals to block sodium transport, he was able to turn off the battery and disrupt limb regeneration.

Borgens has now turned to the larvae of the sea lamprey, a primitive vertebrate that can partially regenerate its spinal cord when it is severed. Borgens, and his coworkers at Yale, Lionel F. Jaffe and Melvin J. Cohen, discovered currents of up to half a milliampere entering the cut surface of lamprey spinal cords immediately after they were severed (the currents declined after that). A current of this level, channeled through the proper resistance, could power one of the light-emitting diodes used in hand held calculators.

That does not mean, says Borgens, that lampreys are an answer to the energy crisis. But the currents are the largest steady biological currents that have been observed in association with development or injury. And the experiment, reported in the February issue of the *Proceedings of the National Academy of Sciences*, offers some hints as to the biological effects of the currents.

Most of the current is caused by the flow of sodium ions; calcium ions may also play a part. Previous research has shown that some of the processes associated with elongation in cells are under ionic control. The currents may also produce a strong enough electric field to cause the migration of cellular bodies such as mitochondria, which tend to aggregate in the area where the cord has been severed.

# Malaria Safari

*From Kenya to New Jersey, from liver to bloodstream, a victim traces the course of drug-resistant malaria*

**by Richard Van Gelder**

On Sunday, March 12, 1978, the American Museum of Natural History's Kenya safari was camped in tents along the Galana River in eastern Tsavo National Park. Before breakfast, some of us went on a long drive along the river's edge, where we had lovely views of graceful, long-necked gerenuks, standing gazing at us from the red termite hills, and rare glimpses of beautiful lesser kudu bucks that observed us from behind screens of green brush. At lunch that day (during which an ostrich invited itself into the dining tent), I dutifully reminded the group that it was Sunday and that everyone should take his or her antimalarial (chloroquine), and carefully took my own. That afternoon, a few of us were rewarded with a sight of a huge leopard as it bounded out of an acacia shrub and brazenly walked off into tall grass.

March 14 was our last day in the field, and we spent it at Lake Jipe, on the Tanzanian border, where we saw a variety of water birds, including the rare pygmy goose. Along the way we had seen oryx, hartebeest, a huge herd of two to three hundred elephants, and even nesting secretary birds. During our seventeen days in Kenya we saw more than 60 species of mammals and 340 species of birds. At dusk that last Tuesday night, I sat on the roof of a lodge at Taita Hills and watched the waterbuck reflected in the waterhole. Far off there was a little flash of white, which I deciphered as the wind ruffling the white mane of a lesser kudu, otherwise invisible in the dark. That evening a mosquito bit me. Since I am seldom bitten by mosquitoes, I remember it clearly. As that mosquito bit, its saliva carried into my blood some tiny organisms that had been waiting in its salivary gland for this moment.

About two weeks earlier, while our group was still in London, that mosquito had bitten someone else in the Taita Hills. Although whoever was bitten probably was not suffering the acute stage of malaria, and even though that person may not have had fevers for years, swimming in his or her blood were crescent-shaped microorganisms, both male and female, of a species of protozoan (one-celled animals) called *Plasmodium falciparum.* The mosquito, a female of the genus *Anopheles,* sucked up some of those crescents along with the victim's blood. Within fifteen minutes the small male crescents had extruded long, whiplike tails and were swimming about in the mosquito's stomach in search of the larger, sedentary female forms. When the males found the females, the whips broke free from the crescents and penetrated the females, which had become rounded. Male and female together formed the equivalent of a fertilized egg.

During the next two weeks, while our group traveled from London through the northern Kenya parks, these cells became embedded in the stomach wall of the mosquito. Each cell divided to produce more and more cells in a wartlike cyst. Perhaps fifty such cysts formed in the mosquito's stomach. Then the cysts burst, and the tiny cells (perhaps 200,000 of them) made their way to the mosquito's salivary glands.

Two nights after my mosquito bite, our safari group flew from the Nairobi airport to London, where we changed planes, and by the afternoon of March 17, I was home again in New Jersey. By this time the organisms passed on to me by the mosquito had found their way to my liver; in the liver cells, they were dividing rapidly and increasing their numbers.

The next six weeks were routine. I caught up on accumulated office work and correspondence, lectured to a graduate seminar at City University, advised the Springfield, Massachusetts, museum on their proposed new African hall, gave a talk about African animals to the fourth grade at the local elementary school, finished a paper on the nomenclature of domestic animals, and worked on my notes on the spiral-horned antelopes. And I also took my children to Acadia National Park in Maine for five days.

During those six weeks, however, something else was happening. The falciparum protozoans spent about eight days in my liver; then, having increased manyfold, they all left my liver and invaded my bloodstream. There they met their first setback. Normally, they would have penetrated my red blood cells to feed on the hemoglobin within them, but also in my blood at this time was chloroquine, which I had continued to take after the trip, and it killed almost all of them. It is those few that did not succumb that have made medical history.

Those few surviving protozoans were different from the other malaria parasites in east Africa: they were resistant to chloroquine. They maintained themselves at low level in my blood, gradually reproducing, not sexually, with males and females, as they had first done in the mosquito, but by

simple division, or splitting. In two days, each protozoan could produce from eight to thirty-two descendants, which then went out to invade more red blood cells.

Eventually, assuming that I had passed the time when any parasites could remain in my blood, I stopped taking chloroquine. Of course, the parasites that did remain, flourished. By April 30, some six weeks after the mosquito had bitten me, there were as many as 200 parasites in every drop of my blood, perhaps a billion in my whole body.

During the night of April 30 I had a chill. It was not severe, but I remember huddling deeper into my covers. When I awoke, I didn't feel well, but I didn't feel all that sick, either, and I went to the office as usual. Early that afternoon I had a headache and felt uncomfortable. I asked one of the other people in the office if there was a virus going around. I was told there was some 24-hour bug and assumed that I had it. I left for home early that afternoon and took a nap. That evening I had a temperature of 102°F. Assuming I had a virus, I started taking aspirin every four hours and drinking lots of fluids. By noon the next day I was well and had no fever. But I had some indigestion, so I stopped taking the aspirin. I awoke the next morning with a temperature of 104.5° and knew I needed medical help. A local doctor examined me, took some blood, and sent me home—back to the aspirin and fluids. He said that if I did not respond, I might have to be hospitalized.

Thursday, May 4, is a haze. I know I had fever and chills, and I was probably delirious. I was lucid long enough, however, to cancel a speech dedicating the new laboratory building at the Quincy Bog Natural Area in New Hampshire on Saturday, and to arrange for another speaker. The next day I was admitted to a local hospital, where, within ten minutes, microscopic examination of a blood smear showed that I had malaria.

Just finding malaria parasites in blood smears is not enough. There are four kinds of human malaria (there are other kinds in birds, monkeys, and rats). Two of these are relatively common; the other two are rare, although widely distributed. Probably the commonest of all is *Plasmodium vivax*, which exists in both temperate and tropical areas. It is usually called tertian or benign tertian malaria because it has a 48-hour fever cycle. (The Romans, from whom we get the word *tertian*, counted the initial day as number one, so forty-eight hours later would be the third, or tertian, day.) The other common type is *P. falciparum*. It has a 40- to 48-hour cycle and is called subtertian, malignant tertian, or aestivo-autumnal malaria. The identification of the kind of malaria is important because the human cycle differs according to the species that is present. In the falciparum malaria, for example, all of the parasites leave the human host's liver and enter the blood system where the rest of their activities take place. In the vivax type, the liver remains a reservoir of infection, although the fevers are caused by the multiplication of parasites in the blood system.

Taxonomy, the science of classification, is a major activity at the American Museum, where I have been a taxonomist for many years. I am often asked what useful purpose taxonomy serves, and now I have another example of the importance of being able to classify animals correctly, this time protozoans.

The slides of my blood were rushed to an expert malaria taxonomist, one whom the Museum retains as a specialist in tropical medicine. He identified the parasites inhabiting my red blood cells as *P. falciparum*. With my fever approaching 105°, I was started immediately on medication, which consisted of large doses of chloroquine for three days. By the end of that time, no malaria organisms could be found in my blood, and after four days in the hospital, I was discharged to recuperate at home from the damage done by the protozoans to my liver and blood.

My recovery was slow, slower than I had expected from my reading about certain explorers who, after a day or two in bed, were up and on the march right away. I was anemic from the destruction of red blood cells by the malaria parasites, my liver was enlarged, and I had other side effects, either from the malaria or the medication, including lack of stamina, indigestion, ringing in the ears, and occasional outbreaks of hives. After a week at home, I went back to working half time at the office, and at the end of May, a month after my first chill, I was working full time.

Falciparum malaria does not remain in the liver and all of the parasites are out in the blood system when the fevers occur; thus, it is very vulnerable to treatment with chloroquine. Although it is the deadliest of all kinds of malaria—Alexander, Borgia, and Cromwell are thought to have been among its victims—falciparum is now the most readily treated. The therapy for vivax malaria, on the other hand, involves not only an attack on the organisms in the blood with chloroquine but also subsequent treatment with another chemical to attack those that remain in the liver.

On June 9 I started driving south to attend the meeting of the American Society of Mammalogists in Athens, Georgia. I had some work to do along the way in Shenandoah and Great Smokies national parks. The first evening in Shenandoah National Park in Virginia, I walked to the top of a small hill to view the sunset and found it unusually hard going. I decided that my past month of inactivity had taken its toll. Two days later, in the Great Smokies, near the border between North Carolina and Tennessee, I started walking to the top of Clingman's Dome, the highest point in the park. It was a mild climb, but I couldn't make it more than halfway. Although I didn't realize it, the pressure I felt in my chest was my enlarged liver, and throughout my blood, malaria parasites were devouring the oxygen-carrying hemoglobin.

Two days later, on the morning of June 13, I was at the meeting of the board of directors of the American Society of Mammalogists, and I complained about the air conditioning being too chilly. An hour of sitting in the hot Georgia sun did not warm me, so I returned to my room and took a nap. When I woke up, I took my temperature. It was 102°. I went to the local university hospital and told the doctors I thought I had malaria again, even though I had presumably been cured. A blood smear was made, and I was examined. Since no parasites were seen in my blood, and there were no indications of malaria from the examination, the doctors suggested that I had a virus. Much relieved to have only a virus, I returned to my room and started on the prescribed aspirin and fluids. By the next day I was well and went to the meetings. But early that afternoon I felt feverish again and went back to my room. My temperature was 102°, and I started on the aspirin once more.

I was very sick the next morning, the 15th, and I called the hospital. They admitted me and within a few minutes had identified malaria parasites in my

# How to buy a typewriter.

Choosing a portable typewriter isn't hard if you know what to look for. This brief guide will help you make the best choice.

**Test the feel.** Check the slope and height of the keyboard. Check the size and shape of the keys. Make sure the controls are uncrowded and easy to reach.

Test the feel of a Smith-Corona® electric typewriter against several other brands. We welcome the comparison.

**Try the touch.** A responsive touch makes for better, easier typing. Look for a touch that is prompt, easy and dependable.

When you test a Smith-Corona, for instance, note how smartly the carriage returns. Press a button—zip—the carriage is back where it started.

**Listen to the sound**—the typewriter is trying to tell you something. If it sounds tinny, beware. This may indicate that the construction is too light.

**Note the look of the type.** Lines and individual letters should be straight. The impression should be crisp, clean and even. The print quality should not vary over the page.

**Check the overall design.** Good design is part of good value, so choose an attractive modern instrument. The Smith-Corona shown is an example of classic, good design.

**Look at the carrying case.** Does it have double walls for air-cushioned protection? Does it have sturdy latches and hinges? The Smith-Corona case does.

**Check the price.** A typewriter that sells for substantially less than others might be substantially less typewriter. If the price difference is minimal, you're probably better off paying a few dollars extra for the typewriter that tests best.

**Ask who makes it.** Smith-Corona makes every single typewriter that bears its name, which is not true of most other brands. So consider the maker's reputation. A company that has a solid reputation will still be around tomorrow and in the future to give your typewriter necessary service and maintenance.

**A note about ribbon systems.** Smith-Corona offers a unique cartridge ribbon and cartridge correction system. It lets you change ribbons in seconds without touching the ribbon. It also lets you correct typing errors neatly, quickly and easily. Not all correction systems produce equally good results. Test and compare.

**Be sure to try the Smith-Corona carbon film ribbon.** We offer a re-usable nylon fabric ribbon, excellent for ordinary typing jobs. This is the only kind of ribbon most portable typewriters offer. But Smith-Corona also offers carbon film ribbon in five colors. It's the kind of ribbon the most expensive office typewriters use, and it's perfect for jobs requiring a crisp, professional look such as term papers or a resume.

More people prefer Smith-Corona electric portables than all other brands combined. After these tests, we think you'll know why.

*Patented Correction Cartridge*

Smith-Corona

blood smears. The laboratory technician, who had had experience with malaria infections in Vietnam, even identified them as *P. falciparum.* The doctor attending me was not able to get in touch with the Museum's New York specialist, who was away, so she contacted the nearby Center for Disease Control in Atlanta. Once more I was given the chloroquine treatment, a somewhat higher dose this time, and again, after a few days, no parasites could be found in my blood. After five days in the hospital in Athens, I flew home. I was extremely weak from anemia but seemed to have suffered no major liver or kidney damage.

The Museum's tropical disease expert was still away, so I visited another specialist. He examined the microscope slides of the parasites that I had brought back and confirmed the identification of *P. falciparum.* The Center for Disease Control also confirmed that this was what I had had both times—except that falciparum malaria is not supposed to recur after treatment, at least not if it has been picked up in east Africa. (Chloroquine-resistant malaria was, however, known from Southeast Asia, and other areas.) There was a suspicion that I may have had a mixed infection of vivax and falciparum malaria, but the specialists had to agree that there was no sign of vivax in any of my blood smears. They began to think that I had not told the truth about taking the medication. During World War II, GI's in the Pacific, unhappy at turning yellow from the atabrine medication then in use, became adept at feigning swallowing the pills and later discarding them. Although chloroquine has no such effects and I knew that I had taken the medication, the doctors also knew that I shouldn't have had falciparum malaria again. They put me on a five-week course of chloroquine once more, trusting me to take the pills and also requiring me to have my blood tested every week.

Again my recuperation was slow. By mid-July, however, I decided that I was well enough to start a mild exercise program, and within a few days was walking a brisk mile in less than fourteen minutes. But I had to stop this regimen when the constraining pressure I had felt before in my chest returned. On July 27 I finished my five weeks of medication, and in August I returned to the office.

There was a lot of accumulated mail, as well as a big pile of scientific journals. Going through *Science,* a weekly published by the American Association for the Advancement of Science, I saw an article by two researchers at Rockefeller University in New York. They had been culturing falciparum malaria parasites in their laboratory, and by adding dilute chloroquine solution to the medium, had found out how rapidly the parasites could develop resistance to chloroquine. Although the amounts of chloroquine they used were minuscule compared with the quantities that had been in my blood, in as little as five weeks, the protozoans were able to withstand three times the dose of chloroquine that had killed them at first.

I wrote to the Rockefeller parasitologists and told them of my case. Even though my doctors did not really believe that I had had resistant malaria from east Africa, indefinable little twinges here and there led me to believe I still had malaria. I told the Rockefeller scientists that, if I did have malaria, my parasites might be of extreme interest to them since they would probably be far more resistant to chloroquine than any that they had cultured in their lab. The Rockefeller scientists wrote that they were interested, but I could also read in their letter their doubts that I had really had a recurrence of falciparum malaria. They suspected that I had had the vivax type. That would explain my relapse since I had not had the therapy that would eliminate the vivax parasites in the liver. Nevertheless, they told me that they would want a blood sample, and how it should be taken, if I had another attack.

On August 22 I awoke as usual at 5:30 but felt a little under the weather. Call it a premonition, but I decided to take a thermometer to the office with me. Together with my son, Russell, who was working as a volunteer in the Museum's photographic archives, I left the house at 6:30, chatting along the way with my usual CB associates, Cookie Monster, Grease Monkey, Caveman, and Humpty Dumpty. About 9:00 I had what I now know is a typical malarial headache and took my temperature—it was 99.4°, not abnormal. Nevertheless, I *knew* I had malaria again and called Russ, who decided to go home with me. By the time we were back in New Jersey, my temperature was down to 98.8°, but I still knew I was having another attack of malaria. I arranged to have a blood smear made at a local hospital, and by early afternoon, they admitted me as a patient, having once more found the parasites in my blood.

We telephoned the New York specialist who had treated me after the second attack, and he had me transferred to a New York City hospital. When I arrived early that evening, I was met by one of the Rockefeller doctors, whom I had called immediately from New Jersey, and I handed him a large plastic container with ice and a sample of my blood that I had had drawn for him as soon as the malaria had been confirmed. By that night, when they finally started giving me medication—large doses of chloroquine again—my temperature was up to 103°.

I was now beginning to make believers out of the experts, but it was hard. The cultures that the Rockefeller researchers had started "took" and began growing and dividing. After two days even they had to admit that I didn't have vivax. They had also excluded one of the rare types. That left falciparum or the other rare type. By the next day they were convinced that I did indeed have falciparum malaria and that I seemed to have one of the first cases of this form from east Africa that was resistant to chloroquine.

Shortly before my trip, a Dane had contracted a case of drug-resistant malaria on a tour in Africa, and later that year a Georgia man, who had been on a safari in Tanzania, came down with malaria that proved resistant to chloroquine. There had been reports of possible drug-resistant malaria cases from east Africa before this, but without solid documentation. The *Morbidity and Mortality Weekly Report* of the Center for Disease Control in Atlanta for November 24, 1978, reported on all three of these cases, saying they "present the strongest evidence to date that chloroquine-resistant *P. falciparum* malaria has appeared in Africa."

While the chloroquine was again knocking down the parasites in my blood those first three days in the New York hospital, samples of my blood were flown to the Center for Disease Control. There they began culturing the parasites and also inoculated a South African owl monkey with some of my blood in hopes of establishing the parasites in that poor creature. My previous records of malaria were extracted (despite an early computer output that showed no record of my

3015-050

case) and the first two attacks were reconfirmed as falciparum.

After a day or two without fever, I began to feel pretty well and had little of the discomfort and weakness that followed the first two attacks. My main problems were a shortage of puncturable veins for the technicians' frequent samples and some soreness around the ribs from their constant probing to find out if my spleen was enlarged (it wasn't, although this is often a characteristic of malaria) and how big my liver was (it was enlarged). I was looking forward to an early return home and was greatly disappointed to find that they were going to keep me in the hospital for a considerable time.

The main experience with chloroquine-resistant malaria has been with strains from Southeast Asia. At the beginning of the Vietnam war about 5 percent of the falciparum malaria in Southeast Asia was resistant. By the time we left, the malaria in that region was more than 95 percent resistant. New medicines to overcome this resistance were developed, but most were so destructive to the patient that they were almost worse than the malaria itself. Ultimately, however, a reasonable Southeast Asian "cure" was developed from a new combination of drugs. And so, two days after I had finished the chloroquine treatment, I was put back on medication, a powerful modification of the Southeast Asian treatment. This continued for five days, and finally, twelve days after I had been admitted, I was allowed to go home to recuperate. It was the beginning of September, almost six months since the Kenya trip, when I was discharged from the hospital.

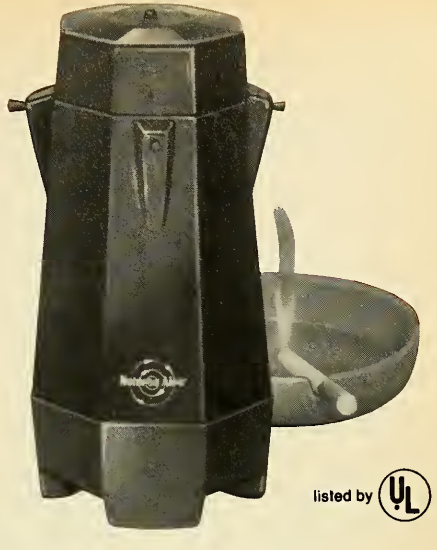
One of the first things that I had asked when it was finally confirmed that I had resistant falciparum malaria was whether anyone else on our tour could have gotten it and not yet have experienced an attack. I was assured by all of the experts that if the other tour members had not come down with it by August, there was no likelihood that they would. I assumed that I would have heard if anyone else on the tour had been sick with malaria, and I had not.

We tend to think of malaria as a tropical disease, but it is not. At one time it ranged throughout most of eastern North America as far north as Quebec, and it has been known to occur as far north as the sixtieth parallel in Russia. The digging of the Erie Ca-

# Now! A Scientific Way to "SCRUB" the Air Clean!

## Clear The Air with "NATURES-AIRE"

### Makes dust, odor and pollutants vanish—leaves the air country fresh



listed by UL

**Discover nature's own "secret" for fresh air...**
Ever notice how wonderfully fresh and clean the air is after a good thunderstorm? Well, it wasn't the rain that cleansed the air... it was the negative ions generated by the storm. Now you bring that same natural phenomenon into your home, office or car with Natures-Aire, the ion generator that works like Mother Nature to cleanse, purify and refresh the air you breathe!

**Natures-Aire—a controlled "thunderstorm"**
That's right! Natures-Aire safely and electronically emits negative ions to create the same beneficial balance of ions found in the great outdoors—right in your home. You just plug it in and it silently and immediately begins to sweep unpleasant odors, smoke and pollutants from the air—leaves it refreshed and smelling sweet and country-fresh.

**Unlike many similar products**
Natures-Aire produces precisely the right balance of ions—25,000/cm3. Scientific research has shown that much more or less would not have the beneficial effect. In fact, Natures-Aire is now the *standard by which Underwriters Laboratories measures other negative ion generators.* It is the first ion generator to receive U.L. listing.

**Negative Ions—Nature's "Good Guys"**
Though you can't see them working, negative ions actually grab on to particles of dust, smoke, organic and inorganic pollutants and sweep them from the air. Just as negative ions cleanse the air after a thunderstorm, Natures-Aire cleanses the air in your home with its gentle, controlled stream of negative ions—Nature's "good guys".

**Natures-Aire—no matter where you live**
Studies show that winds carry harmful pollutants everywhere—even to tucked-away communities. That's why Natures-Aire is so vital for everyone. In the near future, negative ion generators will undoubtedly be standard equipment in airplanes, office and apartment buildings. But you don't have to wait! You can start protecting your whole family from harmful pollutants and unwanted odors right now with Natures-Aire.

**Perfect when you entertain**
You'll love breathing purified air everyday, but imagine what a great benefit Natures-Aire will be when you have parties. No lingering cooking odors to embarrass you—no smoke filled rooms when the guests are gone! Yes, Natures-Aire will actually destroy stubborn odors, smoke, dust and other harmful pollutants in the air—not just cover then up with an artificial "freshener." Lets the whole family breathe easier! Just think what an important difference it will make to your personal environment.

**Proven safe and effective**
Yes, Natures-Aire's graphite conductive fibers are so safe a baby could chew on them. And Natures-Aire sweeps any airborn micron-size pollutants from the air and deposits them in the wall or floor. *So effective at eliminating smoke and odors, you'll notice the pleasant difference in just minutes!*

**Now—Mountain-Aire for your Car, Van, Truck or Boat**
Natures-Aire has a "twin" that works wonders in your car, too. It's called Mountain-Aire. You just plug it into the cigarette lighter of your car and enjoy a smoke-free, odor-free, pollutant-free freshness wherever you go!

**Put your nose to the test without risk!**
You're probably a little skeptical. That's okay—we're so convinced that Natures-Aire and Mountain-Aire are the most effective, revolutionary air purifiers around that we're prepared to offer you a 30-Day Money-Back Guarantee. Prove it to yourself. Use Natures-Aire in your kitchen, bathroom, living room, bedroom (many say they actually sleep better!) and Mountain-Aire in your car and see for yourself if you don't notice the refreshing difference right away.

**Small price—big reward!**
You can own the product of the future for just $79.95. What a small price to pay for clean, invigorating air for years to come! But remember—if you're not absolutely convinced that Natures-Aire and Mountain-Aire far out-pertorm other air purifying systems, simply return your order for a prompt, courteous refund.

**Pure air...Pure value!**
Imagine! For fresh, pure air every day of your life—you pay just $79.95. *A small investment when it comes to protecting the well-being of your whole family!*

**Safe enough for a baby**... yet effective enough to rid your home of lingering smoke, odors and pollutants. Leaves it wonderfully refreshed and sweet smelling!

nal was almost not completed because of the presence of malaria in the Montezuma Marshes (now a wildlife refuge) in upstate New York. In 1935 there were more than 4,400 deaths from malaria in the United States. By 1946 the total had been reduced to 341. At present all of the malaria in the United States comes from outside the country. In 1977 there were 480 cases of malaria reported (as required by law) to the Center for Disease Control. About one-third were acquired in Africa, and more than half were caused by *P. falciparum,* and of these, two cases ended in death. Of twenty people on a 1977 Kenya tour similar to ours, three did not take chloroquine as a preventive. Each of the three came down with falciparum malaria and one died within three days, never having sought treatment.

Malaria is considered to have been one of mankind's greatest killers. Association with night air was made early, and the name *malaria* itself refers to "bad air." Another association was made with swampy regions. Although swamps are breeding places for mosquitoes, the damp night air, not the insects, was generally thought to convey the disease.

All who have been to Africa remember the tall, yellow-barked acacia trees that grow along streamsides. The early explorers called these acacias "fever-trees," a name we still use. In the past, overnight camping near these acacias was sure to result in illness.

A French Army physician in Algeria, Charles Louis Alphonse Laveran, discovered the malaria organism in 1880, just a century ago, but it was not until 1898 that Ronald Ross proved that the malaria parasites were dependent upon certain mosquitoes for their transmission. Both Laveran and Ross won Nobel Prizes—Ross in 1902 and Laveran in 1907. Since Ross, the war against malaria has largely involved two aspects—control of mosquitoes and chemotherapy against the disease in humans. The greatest success in the war against malaria came in the years after the Second World War, when the combined availability of DDT for mosquito control and chloroquine for prevention and therapy served to reduce the disease to its lowest level in history. Indeed, public health officials hoped that they would soon see malaria totally eliminated from the earth and projected 1960 as the year in which malaria infections would be reduced by 90 percent worldwide.

Alas, that hope is now gone. Not only has there been an increase in the resistance of the protozoans to chloroquine, as I know all too well, but mosquitoes have become more resistant to DDT. The economics of the current energy crisis has also affected malaria-control programs, with some of the poor nations giving up altogether for lack of funds. And a very human problem has occurred in many regions where, despite the funds provided, the money seems to have disappeared into the pockets of officials without any control activity taking place.

Evidence of the losing battle appears in the figures of nearly 500 cases in the United States in 1977, and 1,500 cases in England, which has much greater traffic from malaria zones. In the decade prior to 1973, the annual number of civilian cases of malaria in the United States was a fairly constant 100 to 200, but it rose to 302 in 1973 and to 480 in 1977. Specialists, noting a growing incidence in places where the disease had been at low levels not too long ago, estimate more than 150 million cases of malaria will occur this year, with a million deaths in Africa alone.

The fight against malaria continues, however. The emphasis has shifted to attempts to find a vaccine that will prevent humans from coming down with the disease. The development in recent years of a means of culturing falciparum malaria in vitro and the ability to infect owl monkeys with the parasites have aided progress toward a vaccine. But problems remain. For one thing, the protozoans go through varied phases in the human body, and each form can cause different immune reactions by the host and respond differently to experimental vaccines. Another major problem is that, unlike the response of the body to bacterial and virus infections, immunological response to parasites is slow, and to introduce the vaccine to the immune system it is necessary to use a stimulant, called an adjuvant. Under experimental conditions, monkeys injected with vaccine and adjuvant are known to have survived malaria infections sufficiently to indicate that they received marked protection from the injections —but they suffered terrible side effects from the adjuvant, making it unacceptable for human use. A search is on to modify or eliminate the adjuvant as a route to a successful vaccine, and laboratories in several parts of the world are hard at work on this problem. For the investigators, a Nobel Prize may be the reward. For the rest of us, the savings of millions of lives from the worst of human parasites is the stake.

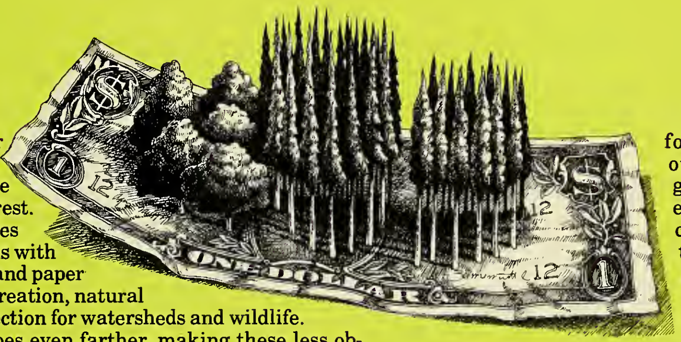
What is the cost of malaria? For me, it meant ninety-two days out of work, twenty of which I spent in hospitals. Thanks to a vast accumulation of sick leave, I was paid my salary for work I didn't do, and my health insurance paid thousands of dollars for hospital and doctors' bills, incidental lab fees, and medication. In addition, there were expenses to my family that would not have been incurred had I been healthy. I also lost income from consultation, writing, and lecturing fees. All in all, the minimum direct cost of my case was in excess of $27,000. The indirect losses may be even greater because, among other things, a year of recuperation has delayed my return to Africa to continue my studies of antelopes in Botswana, and I have lost contact with my identifiable animals. While neither salaries nor hospital expenses are so high in the third world countries where malaria is most prevalent, one can readily imagine the drain that the 150 million annual cases have on the economies of those nations.

It was certainly no fun to have malaria or to see myself written up in the Center for Disease Control's *Morbidity and Mortality Weekly Report* or in the *Journal of the American Medical Association* as "a 49-year old zoologist. . . ." It was frightening to roll around with the "sweats," have a 104.5° fever, and experience what I can only call premature senility during my ever-so-slow recuperation. And, although I have been free of malaria symptoms since September, and trust that I am cured, I have to stay healthy until next September to convince the doctors. On the other hand, there has been some intellectual challenge and I have broadened my knowledge of another zoological area. And, in the test tubes at Rockefeller University and in some monkeys at the Center for Disease Control, "my" falciparum may be growing and dividing and may someday lead to the development of a safe vaccine for this scourge, and perhaps a Nobel Prize for the investigators. That's as close as I'll ever get to it.

*Richard Van Gelder, curator of mammals at the American Museum of Natural History, is a frequent traveler to Africa. He had never contracted malaria before.*

# Money does grow on trees.

## (And vice versa.)



Consider the wonderfully versatile American forest.

It provides all Americans with useful wood and paper products, recreation, natural beauty, protection for watersheds and wildlife.

But it goes even farther, making these less obvious, but no less important, contributions to the country's economic well-being:

**Jobs** — millions of workers in the woods, in the factories that turn wood and fiber into thousands of essential products, and on construction sites all over this growing land.

**Taxes** — billions of dollars a year, going to support schools, hospitals, public safety, countless other vital public services.

**International trade** — wood products we export help strengthen the American dollar and improve the nation's balance of payments.

**Inflation deterrent** — the more productive the forest, the more likely that the nation's supply of wood and paper products will be adequate to meet sharply increasing demands — and will be available at reasonable prices. Thus, a productive commercial forest, growing trees for today *and* tomorrow, becomes a significant inflation fighter.

### Your stake in the commercial forest

So every American has a stake in increasing the productivity of the commercial forests. (*Commercial forest*, as defined by the U.S. Forest Service, is *all* forestland — whether owned by individuals, government or the forest industry — that is capable of, and potentially available for, growing repeated crops of trees for harvest. It includes land in National Forests but not in National Parks or Wilderness areas.)

So far, the commercial forest has been able to cope with all the demands made on it. But we can't expect it to continue to provide its benefits automatically.

### Why trees need money too

If wood supply is to keep up with the predicted doubling of demand in this nation over the next 50 years, expenditures for replanting and regeneration will have to be substantially increased.

And the greatest potential for improvement is on publicly held land.

So that means the nation needs to establish policies and take actions to encourage productivity — not only in the National Forests but in other forests as well.

If you'd like to be better informed on how important it is to keep America's forests productive, write American Forest Institute, P.O. Box 873, Springfield, VA 22150 for a free booklet, "The Great American Forest."

The great American forest. Trees for tomorrow. And tomorrow. And all the tomorrows after that.

**Trees. America's renewable resource.**

# The First Forebear

*Did we multicellular creatures evolve by division or amalgamation?*

**by Stephen Jay Gould**

I spent the last day of our late and largely unlamented decade reading through a stack of New York Sunday papers for the last weekend of the 1970s. Prominently featured, as always in the doldrums of such artificial transition, were lists of predictions about "ins" and "outs": What will the eighties reject that the seventies treasured? What, despised during the seventies, will the eighties rediscover?

This surfeit of contemporary speculation drove my mind back to the biological ins and outs of the last transition between centuries. The hottest subject of biology in the last century did suffer a pronounced eclipse in our times. Yet I happen to maintain a strong fondness for it. I also believe that new methods will revive it as a major concern for the remaining decades of our century.

Darwin's revolution led a generation of nineteenth-century natural historians to view the reconstruction of life's tree as their most important evolutionary task. They did not focus narrowly upon little twiglets (the relation of lions to tigers) or even upon ordinary branches (the link between cockles and mussels). They sought to root the trunk itself and to identify its major limbs: How are plants and animals related? From what source did the vertebrates spring?

In their mistaken view, these naturalists also possessed a method that could extract the answers they sought from the spotty data at their disposal. For, under Haeckel's "biogenetic law"—ontogeny recapitulates phylogeny—an animal climbs its own family tree during the development of its embryo. The simple observation of embryos should reveal a parade of adult ancestors in proper order. (Nothing is ever quite so uncomplicated, of course. The recapitulationists knew that some embryonic stages represented immediate adaptations, not ancestral reminiscences; they also understood that stages could be mixed up, even inverted, by unequal rates of development among different organs. Yet they believed that such "superficial" modifications could always be recognized and subtracted, leaving the ancestral parade intact.) E.G. Conklin, who later became an opponent of "phylogenizing," recalled the beguiling appeal of Haeckel's law:

> Here was a method which promised to reveal more important secrets of the past than would the unearthing of all the buried monuments of antiquity—in fact nothing less than a complete genealogical tree of all the diversified forms of life which inhabit the earth.

But the turn of the century heralded the collapse of recapitulation. It died primarily because Mendelian genetics (rediscovered in 1900) rendered its premises untenable. (The "parade of adults" required that evolution proceed only by an addition of new stages to the end of ancestral ontogenies. But if new features are controlled by genes, and these genes must be present from the very moment of conception, then why shouldn't new features be expressed at any stage of embryonic development or later growth?) The assumption that ancestral reminiscences could always be distinguished from recent embryonic adaptations had not been sustained. Too many stages were missing, too many others discombobulated. The application of Haeckel's law produced endless, unresolvable, fruitless argument, not an unambiguous tree of life. Some tree builders wanted to derive vertebrates from echinoderms, others from annelid worms, still others from horseshoe crabs. E.B. Wilson, apostle of the "exact," experimental method that would supplant speculative phylogenizing, complained in 1894:

> It is a ground of reproach to morphologists that their science should be burdened with such a mass of phylogenetic speculations and hypotheses, many of them mutually exclusive, in the absence of any well-defined standard of value by which to estimate their relative probability. The truth is that the search . . . has too often led to a wild speculation unworthy of the name of science; and it would be small wonder if the modern student, especially after a training in the methods of more exact sciences, should regard the whole phylogenetic aspect of morphology as a kind of speculative pedantry unworthy of serious attention.

Phylogenizing fell from general favor, but you can't keep an intrinsically exciting subject down. (I speak of high-level phylogenizing—the trunk and limbs. For twigs and small branches, where evidence is more adequate, work has always proceeded apace, with more assurance and less excitement.) We didn't need "Roots" to remind us that genealogy exerts a strange fascination over people. If uncovering the traces of a distant great-grandparent in a small overseas village fills us with satisfaction, then probing further back to an African ape, a reptile, a fish, that still-unknown ancestor of vertebrates, a single-celled forebear, and even to the origin of life itself can be awesome. Unfortunately, the further back we go the more fascinated we become and the less we know. In this column, I will discuss one classic issue in phylogenizing. It is an example of the joys and frustrations of a subject that will not go away: the origin of multicellularity in animals.

Ideally, we might hold out for a simple, empirical resolution of the issue. A sequence of fossils perfectly intermedi-

If your interest is only in buying an instant camera for as little as possible, you've stopped at the wrong ad. Polaroid's SX-70 Sonar Land camera isn't cheap. On the other hand, if the idea of owning the finest instant camera in the world appeals to you, we'll tell you more.

In brief, the Polaroid SX-70 Sonar is perhaps the most ingenious, yet easy-to-use picture-taking system ever designed. It incorporates a computer, electronic eye, motor, film developing capacity and a revolutionary sonar focusing system: a photographic breakthrough that lets you take pictures at any point from infinity to 10.4 inches without changing, adjusting or calculating anything.

You push a button. An ultrasonic impulse speeds from the camera to the subject and back. In milliseconds the sound bounce-back is computed and the camera automatically focuses itself. Simultaneously the electric eye sets the exposure. And in about one second, the camera hands you a precisely focused, properly exposed, developing photograph.

And with the capacity to do all of that, it still folds down to a portable 1 by 4 by 9 inches. Handsomely covered in leather and brushed chrome.

And if by now all of this is beginning to sound like a wonderful bargain, it's obvious you're the kind of person who can discern the difference between the value of something, and its price.

# When you stop thinking about the price, you're beginning to appreciate the value.

*Enter the world of Questers nature tours.*

When you travel with Questers, you have the advantage of our knowledge of the travel world. And our experience of the natural world. We are travel professionals. And our only tour program is Worldwide Nature Tours.

Under the leadership of an accompanying naturalist, we search out the plants and animals, birds and flowers... rain forests, mountains, and tundra... seashores, lakes, and swamps of the regions we explore. At the same time, we include the more usual attractions in touring—the cities, archaeological sites, and people.

The current Directory of Worldwide Nature Tours describes 29 tours varying from 9 to 36 days and going to virtually every part of the world. Included are The Amazon, Peru, Patagonia, Galapagos, Hawaii, Alaska, Death Valley, Everglades, Ladakh, Sri Lanka, Iceland, Scotland, Greece, Australia, and New Zealand. Tour parties are small, the pace leisurely, and itineraries unusual.

*Call or write Questers or see your Travel Agent today for your free copy of the Directory of Worldwide Nature Tours.*

ate between a protist (single-celled ancestor) and a metazoan (multicelled descendant) would erase all doubt. But the transition occurred in unfossilizable, soft-bodied creatures long before the inception of an adequate fossil record. The first metazoan fossils from some 600 million years ago do not surpass the most primitive modern metazoans in their similarity to protists. We must turn to living organisms, hoping that some multicelled descendants still have appropriate marks of ancestry.

Genealogical reconstructions are based on the similarities between postulated relatives. "Similarity," unfortunately, is not a simple concept. It arises for two fundamentally different reasons. The construction of evolutionary trees requires that the two be rigorously separated, for one indicates genealogy while the other simply misleads us. Two organisms may maintain the same feature because both inherited it from a common ancestor. These are *homologous* similarities, and they indicate "propinquity of descent," to use Darwin's words. Forelimbs of people, porpoises, bats, and horses provide the classic example of homology in most textbooks. They look different, and do different things, but are built of the same bones. No engineer, starting from scratch each time, would have built such disparate structures from the same parts. Therefore, the parts existed before the particular set of structures now housing them: they were, in short, inherited from a common ancestor.

Two organisms may also share a feature in common as a result of separate but similar evolutionary change in independent lineages. These are *analogous* similarities; they are the bugbear of genealogists because they confound our naïve expectation that things looking alike should be closely related. The wings of birds, bats, and butterflies adorn most texts as a standard example of analogy. No common ancestor of any pair had wings.

Our difficulties in identifying the trunks and limbs of life's tree do not record muddled thinking about methods. All eminent naturalists, from Haeckel on (and even before) stated their procedure correctly: separate homologous from analogous similarity, discard analogies, and build genealogy from homology alone. Haeckel's law was a procedure, unfortunately wrong, for the recognition of homology. The goal is, and has been, clear enough.

In a broad sense, we know how to identify homology. Analogy has its limits. It may build striking external, functional similarity in two unrelated lineages; but it does not modify thousands of complex and independent parts in the same way. At a certain level of precision, similarities must be homologous. Unfortunately, we rarely have enough information to be confident that this required level has been attained. When we compare primitive metazoans with different protists as potential relatives, we often work with only a few features held in common for any contrast—too few to be sure about homology. Moreover, small genetic changes often have profound effects upon external, adult form. Therefore, a similarity that looks too uncanny and complex to arise more than once may actually record a simple and repeatable change. Most importantly, we aren't even comparing the right organisms, but only pale reflections of them. The transition from protist to metazoan occurred more than 600 million years ago. All true ancestors and original descendants disappeared eons ago. We can only hope that their essential, identifying features have been retained in some modern forms. Yet, if retained, they have surely been modified and overlain with a plethora of specialized adaptations. How can we separate original structure from later modification from new adaptation? No one has ever found an unfailing guide.

Only two scenarios have been favored for the origin of metazoans from protists: in the first (amalgamation), a group of protistan cells came together, began to live as a colony, evolved a division of labor and function among cells and regions, and finally formed an integrated structure; in the second (division), cellular partitions formed within a single protistan cell. (A third potential scenario, repeated failure of daughter cells to separate following cell division, has few takers these days.)

We immediately come up against the problem of homology. Did multicellularity arise only once? Or several times? When we decide how it arose once in the most primitive animal, have we explained its occurrence in all animals? In other words, is the multicellularity of various animal lineages homologous or analogous?

The metazoan group usually regarded as most primitive, the sponges, arose by the first scenario, amalgamation. Modern sponges are little more

# THE JOY OF SETS.

**Another terrific offer from QPB: not just single volumes, but whole sets of books by some of your favorite writers. Tolkien. Hellman. Irving. Singer.**

**These are the books you want to read and own—and they cost up to 65% less than the hardcover editions. (You don't judge a book by its cover, so why pay for the cover?)**

**Great books, great writers, great savings. Isn't QPB your kind of book club?**

**151. The Lord Of The Rings** J.R.R. Tolkien. (3 Vols., Boxed) Hardcover: $32.95 **QPB: $9.95**

**200. The Art Of Cooking For Two** Coralie Castle and Astrid Newton Illustrated by Sara Raffetto and **One Pot Meals.** Margaret Gin. Drawings by Rik Olson. (2 Vols.) **QPB: $8.45**

**621. Maigret And The Killer** and **Maigret And The Madwoman** (2 Vols.) Georges Simenon **QPB: $4.95**

**517. God And The Astronomers** and **Until The Sun Dies.** (2 Vols.) Robert Jastrow. Hardcover: $16.90 **QPB Ed: $7.95**

**570. Three: An Unfinished Woman —Pentimento—Scoundrel Time** (1 Vol.) Lillian Hellman. With new commentaries by the author Introduction by Richard Poirier Hardcover: $16.95 **QPB: $7.95**

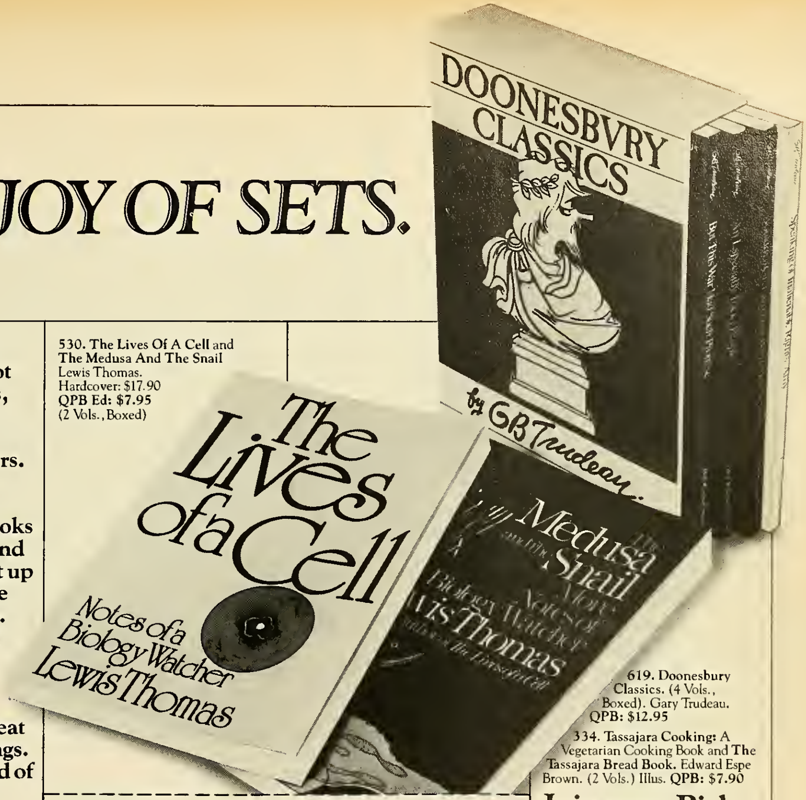
**599. The Awakened Eye** and **The Zen Of Seeing:** Seeing/Drawing as Meditation. (2 Vols.) Drawn and handwritten by Frederick Franck Hardcover: $20.95 **QPB: $8.50**

**602. Enemies, A Love Story** and **Old Love.** (2 Vols.) Isaac Bashevis Singer. Hardcover: $21.90 **QPB: $8.95**

**617. Heaven's Command:** An Imperial Progress/**Pax Britannica:** The Climax of an Empire/**Farewell The Trumpets:** The Decline of an Empire. (3 Vols.) James Morris Hardcover: $38.40 **QPB: $17.95**

**618. Three By Irving:** *Setting Free the Bears, The Water-Method Man, The 158-Pound Marriage.* (1 Vol.) John Irving. Hardcover: $15.95 **QPB Ed: $9.95**

**530. The Lives Of A Cell** and **The Medusa And The Snail** Lewis Thomas. Hardcover: $17.90 **QPB Ed: $7.95** (2 Vols., Boxed)



**619. Doonesbury Classics.** (4 Vols., Boxed). Gary Trudeau. **QPB: $12.95**

**334. Tassajara Cooking:** A Vegetarian Cooking Book and **The Tassajara Bread Book.** Edward Espe Brown. (2 Vols.) Illus. **QPB: $7.90**

## Let's try each other for 6 months.

**Quality Paperback Book Club, Inc., Middletown, Pa. 17057.** Please enroll me in QPB and send the 3 choices I've listed below. Bill me $3, plus shipping and handling charges. I understand that I am not required to buy another book. You will send me *QPB Review* (if my account is in good standing) for 6 months. If I have not bought and paid for at least 1 book in every six-month period, you may cancel my membership. A shipping and handling charge is added to each shipment. QB113-5

**Indicate by number the 3 books or sets you want** ☐ ☐ ☐

Name____________________ 0-16

(Please print clearly)

Address____________________ Apt.______

City__________ State________ Zip______

**How membership works.**

1. You receive **QPB Review** 15 times each year (about every 3½ weeks). Each issue reviews a *new* Main Selection, plus scores of Alternates. All Main Selections with established publisher's list prices are offered at at least 20% discount off that list price.
2. If you want the **Main Selection** do nothing. It will be shipped to you automatically. If you want one or more Alternate books—or no book at all—indicate your decision on the reply form always enclosed and return it by the date specified.
3. **Bonus books for Bonus Points.** For each book or set you take (except the first 3 you get for $1 each), you earn Bonus Points which entitle you to choose any of the books we offer; you pay only shipping and handling charges.
4. **Return privilege.** If *QPB Review* is delayed and you receive the Main Selection without having had 10 days to notify us, you may return it for credit at our expense.
5. **Cancellations.** You may cancel membership at any time by notifying QPB. We may cancel your membership if you elect not to buy and pay for at least one book in every six-month period.

## Join now. Pick any 3 books or sets for $1 each—with no obligation to buy another book.

**624. The Bantam Great Outdoors Vacation And Lodging Guide** Eastern United States and Western United States and Alaska. (2 Vols.) Val Landi. **QPB: $13.50**

## Other titles of interest.

**615. The Decade Of Women:** A Ms. History of the Seventies in Words and Pictures. Edited and Produced by Suzanne Levine and Harriet Lyons, with Joanne Edgar, Ellen Sweet, Mary Thom. Introduction by Gloria Steinem. Hardcover: $17.95 **QPB: $8.25**

**598. The American Image** Photographs from the National Archives, 1860-1960. National Archives Trust Fund Board. With an Introduction by Alan Trachtenberg Hardcover: $20 **QPB: $8.95**

**614. Militant Islam.** G. H. Jansen Hardcover: $8.95 **QPB: $3.95**

QPB

**The first book club for smart people who aren't rich.**

than loosely knit federations of flagellated protists. In some species, cells can even be disaggregated by passing the sponge through a fine silk cloth. The cells then move independently, reaggregate into small clumps, differentiate, and regenerate an entire new sponge in its original form. If all animals arose from sponges, then multicellularity is homologous throughout our kingdom, and it arose by amalgamation.

But most biologists regard sponges as an evolutionary dead end without subsequent descendants. Multicellularity is, after all, a prime candidate for frequent, independent evolution. It displays primary features of analogous similarity: it is reasonably simple to accomplish, it is highly adaptive, and it is the only potential path to the benefits it confers. Ostrich eggs notwithstanding, single cells cannot become very large. The earth's physical environment contains scores of habitats available only to creatures beyond the size limit of a single cell. (Consider only the stability that arises from being large enough to enter a realm where gravity overshadows the forces that act upon surfaces. Since the ratio between surface and volume declines with growth, increasing size is the surest path to this realm.)

Actually, multicellularity evolved separately in the three great higher kingdoms of life (plants, animals, and fungi), and it probably arose several times in each kingdom. Most biologists agree that all origins within plants and fungi occurred by the amalgamation of protistan colonies. Sponges also arose by amalgamation. May we then close the issue and state that multicellularity, although analogous both across and within kingdoms, evolved in the same basic way each time. Modern protists include colonial forms that display both regular arrangement of cells and incipient differentiation. Remember the *Volvox* colonies of high school biology labs? (I must confess that I don't. I attended a public high school in New York just before *Sputnik* went up. We had no lab at all, although it arrived in a flash just as I left.) Some volvoxes form colonies with a definite number of cells arranged in a regular manner. The cells may differ in size, and reproductive function may be confined to cells at one end. Is it such a big step to a sponge?

Only among animals may we make a good case for another scenario. Did some animals, ourselves included, arise by division? This question cannot be answered until we resolve one of the oldest riddles in zoology: the status of the phylum Cnidaria (corals and their allies, but also including the beautiful, transluscent Ctenophora, or comb-jellies). Almost everyone agrees that the Cnidaria arose by amalgamation. The dilemma resides in their relationship with other animal phyla. Almost all possible schemes have their supporters: cnidarians as descendants of sponges and ancestors of nothing else; cnidarians as a separate branch of the animal kingdom without descendants; cnidarians as the ancestors of all "higher" animal phyla (the classical view of the nineteenth century); cnidarians as degenerate descendants of a higher phylum. If either of the last two schemes can ever be established, then our issue is settled—all animals arose by amalgamation, probably twice (sponges and everything else). But if the "higher" animal phyla are not closely related to cnidarians, if they represent a third, separate evolution of multicellularity in the animal kingdom, then the scenario of division must be seriously considered.

Supporters of a separate origin for the higher animals generally cite the platyhelminths (flatworms) as a potentially ancestral stock. Earl Hanson, a biologist at Wesleyan University, has been a leading crusader, both for a platyhelminth origin of higher animals and for the scenario of division. If his iconoclastic view prevails, then the higher animals, including humans of course, are probably the only multicellular products of division, rather than amalgamation.

Hanson has pursued his case by studying the similarities between a group of protists known as ciliates (including the familiar *Paramecium*) and the "simplest" of flatworms, the Acoela (named for their failure to develop a body cavity). Many ciliates maintain large numbers of nuclei within their single cell. If cellular partitions arose between the nuclei, would the resulting creature be enough like an acoelous flatworm to justify a claim for homology?

Hanson documents an extensive set of similarities between the multinucleate ciliates and the multicellular acoeles. Acoeles are tiny marine flatworms. Some can swim, and a few live in water up to 800 feet in depth. But most crawl along the sea bottom in shallow water, living under rocks or in sand and mud. They are similar in size to the multinucleate ciliates. The internal similarities of ciliates and acoeles reside primarily in their shared simplicity, for acoeles, unlike conventional metazoans, lack both a body cavity and the organs associated with it. They have no permanent digestive, excretory, or respiratory system. Like the ciliate protists, they form temporary food vacuoles and perform digestion within them. Both ciliates and acoeles divide their bodies roughly into inner and outer layers. Ciliates concentrate their nuclei in the inner layer. Acoeles devote an inner region to digestion and reproduction and an outer region to locomotion, protection, and the capture of food.

The two groups also display some outstanding differences. Acoeles build a nerve net and reproductive organs that can become quite complex. Some have penises, for example, and impregnate each other hypodermically through the body wall. They undergo embryonic development after fertilization. Ciliates, by contrast, have no organized nervous system. They divide by fission and have no embryology, although they do indulge in sex via a process called conjugation. (In conjugation, two ciliates come together and exchange genetic material. They then separate and each divides later to form two daughters. Sex and reproduction, combined in nearly all metazoans, are separate processes in ciliates.) Most prominently, of course, acoeles are cellularized; ciliates are not.

These differences should not debar a hypothesis of genealogical relationship. After all, as I argued previously, contemporary ciliates and acoeles are more than half a billion years beyond their potential common ancestor. Neither represents a transitional form in the origin of multicellularity. The debate centers instead on the similarities and on the oldest and most basic issue of all: are the similarities homologous or analogous?

Hanson argues for homology, claiming that the simplicity of acoeles is an ancestral condition within the flatworms. His detractors reply that the simplicity of acoeles is a secondary result of their "regressive" evolution from more complex platyhelminths, which have intestines and excretory organs.

Unfortunately, the similarities that Hanson cites are of the sort that always produce unresolvable wrangling about homology versus analogy. Many are based upon the *absence* of com-

# *Take the BASIC ASTRONOMY LIBRARY for only $2.95 (a $61.75 value)*

## *with trial membership in Astronomy Book Club*

Membership Benefits • In addition to getting the BASIC ASTRONOMY LIBRARY for $2.95 when you join, you keep saving substantially on the books you buy. • Also, you will immediately become eligible to participate in our Bonus Book Plan, with savings of at least 70% off publishers' prices. • At 3–4 week intervals (16 times per year) you will receive the Book Club News, describing the coming Main Selection and Alternate Selections, together with a dated reply card. • If you want the Main Selection do nothing and it will be sent to you automatically. • If you prefer another selection, or no book at all, simply indicate your choice on the card, and return it by the date specified. • You will have at least 10 days to decide. If, because of late mail delivery of the News, you should receive a book you do not want, we guarantee return postage.

L-AB4 Natural History

Please accept my application for trial membership and send me the BASIC ASTRONOMY LIBRARY for $2.95. I agree to purchase at least three additional Selections or Alternates during the first 12 months I am a member. Savings range up to 30% and occasionally even more. My membership is cancelable any time after I buy these three books. A shipping and handling charge is added to all shipments.

Please send me the BASIC ASTRONOMY LIBRARY (10115) for $2.95.

**No-Risk Guarantee:** If you are not satisfied—for any reason—you may return your books within 10 days and your membership will be canceled and you will owe nothing.

# Take this 5-volume Basic Astronomy Library for $2.95 (a $61.75 value)

if you will join **Astronomy Book Club** now for a trial period and agree to buy 3 more books—at handsome discounts—over the next 12 months.

Black holes, quasars, pulsars, supernovae, white dwarfs—explore the fantastic discoveries being made about the universe with this outstanding selection of five critically acclaimed astronomy books. Together they form a marvelously comprehensive Basic Astronomy Library—a library which will allow you to tour our cosmos—from the Red Planet to the Seyfert galaxies . . . from the Earth's core to a black holes horizon . . . from how the universe was born to how, when, and where it will die.

Here is what your library will include:

**THE ILLUSTRATED ENCYCLOPEDIA OF ASTRONOMY AND SPACE.** Revised edition. Edited by Ian Ridpath. Your window to the universe. Over 1,000 entries and 150 photographs and illustrations. Hardbound.

**ASTRONOMY: An Introduction for the Amateur Astronomer.** By Jacqueline Mitton. From the fundamentals of physical, chemical and optical laws to stellar evolution. Hardbound.

**STAR ATLAS.** Jacqueline and Simon Mitton tell you how to locate over 4,000 stars. Softbound.

**BLACK HOLES: The Edge of Space, the End of Time.** By Walter Sullivan. Bottomless pits into which whole stars can disappear . . . *Black Holes* takes you on an incredible journey that will change your picture of the universe. Hardbound.

**CATALOGUE OF THE UNIVERSE.** By Murdin and Allen. A portrait of the best known and most remarkable objects in space. More than 300 photographs. Hardbound.

. . . quite a trip for only $2.95—and that's just the beginning!

Of the hundreds of books submitted to us each year, only the very finest are selected and offered to you as a club member.

**Astronomy Book Club** discounts range up to 30% off publishers' prices and sometimes even more. As a member, you'll also immediately become eligible for our Bonus Book Plan, with savings up to 70% off!!

Discover the phenomena of space—join **Astronomy Book Club** today . . . it's a trip!

If reply card has been removed, please write to: ***Astronomy Book Club,*** Dept. L-AB4, Riverside, N.J. 08370 to obtain membership information and an application.

plexity in acoeles, and evolutionary loss is easy and repeatable.

Moreover, the simplicity of acoeles is a predictable result of their small body size. Many physiological functions, including breathing, digestion, and excretion, must proceed through surfaces and serve the entire body's volume. Large animals have such a low ratio of external surface to internal volume that they must evolve internal organs to provide more surface. (Functionally, lungs are little more than bags of surface for exchange of gases, while intestines are sheets of surface for the passage of digested food.) But small animals maintain such a high ratio of external surface to internal volume that they often can breathe, feed, and excrete through the external surface alone. The smallest representatives of many phyla also lose internal organs. *Caecum*, for example, the smallest snail, has lost its internal respiratory system entirely and takes in oxygen through its external surface.

Other similarities, cited by Hanson, may be homologous, but these are so widespread among other creatures that they merely illustrate the broader affinity of all protists with all metazoans, not any specific pathway of descent.

Hanson is well aware that he cannot prove his intriguing hypothesis with the classical evidence of morphology and function. "The best we can say," he concludes, "is that many suggestive similarities are present [between ciliates and acoeles], but no rigorously definable homologies."

Is there another method that might resolve the issue or are we permanently condemned to unresolvable wrangling? Fortunately, we now have a potential source of such information—the DNA sequence of comparable proteins. All protists and metazoans share many homologous proteins. Each protein is built of a long chain of amino acids; each amino acid is coded by a sequence of three nucleotides in DNA. Thus, the DNA code for each protein may contain hundreds or thousands of nucleotides in a definite order.

Evolution proceeds by substitution of nucleotides. After two groups split from a common ancestor, their nucleotide sequences begin to accumulate changes. The number of changes seems to be at least roughly proportional to the amount of time since the split. Thus, overall similarity in nucleotide sequence for homologous proteins may measure the extent of genealogical separation. A nucleotide sequence is a homologizer's dream.

Techniques are just now becoming available for the routine sequencing of nucleotides. I believe within ten years we will be able to take homologous proteins from all the ciliate and metazoan groups at issue, sequence them, measure the similarities between each pair of organisms, and obtain greater insight (perhaps even resolution) for this old genealogical mystery. If acoeles are most similar to protist groups that might achieve multicellularity by evolving cell membranes within their bodies, then Hanson will be vindicated. But if they are closest to protists that can reach multicellularity by integration within a colony, then the classical view will prevail, and all metazoans will emerge as the products of amalgamation.

The study of genealogy has been unfairly eclipsed in our century by the analysis of adaptation, but it cannot lose its power to fascinate. Simply consider what Hanson's scenario implies about our relationship with other multicellular organisms. Few zoologists doubt that all higher animals achieved their multicellular status by whatever method the flatworms followed. If acoeles evolved by the cellularization of a ciliate, then our multicellular body is the homolog of a single protistan cell. If sponges, cnidarians, plants, and fungi arose by amalgamation, then their bodies are the homologs of a protistan colony. Since each ciliate cell is the homolog of an individual cell in any protistan colony, we must conclude—and I do mean this literally—that the entire human body is the homolog of a single cell in a sponge, coral, or plant.

The curious paths of homology go further back. The protistan cell itself may have evolved from a symbiosis of several simpler prokaryotic (bacterial or blue-green algal) cells. Mitochondria and chloroplasts seem to be the homologs of entire prokaryotic cells. Thus, each cell of any protist, and each cell in any metazoan body, may be, by genealogy, an integrated colony of prokaryotes. Shall we then view ourselves both as a congeries of bacterial colonies and as the homolog of a single cell in a sponge or onion skin? Think upon it next time you swallow a carrot or slice a mushroom.

**Until others make theirs like ours, only Zeiss will be guaranteed for life.**

In an industry where quality prevails, doesn't it make you wonder why Zeiss and only Zeiss guarantees its binoculars for a lifetime?

Sound like a high-risk commitment? It isn't at all. It's 134 years of optical leadership, 200 superbly engineered parts, 1800 operations and grueling inspections to insure the highest level of optical and mechanical performance, resistance to climate variations, and complete freedom from internal reflections, ghost images and other disturbing image deteriorating problems under all lighting conditions. And a meticulous choice of materials. With this background and fail-safe procedure, the odds are in our favor that the workmanship and materials will last as long as what they make.

And what they make is a pair of binoculars that will always transmit more light than any other; focus with incomparable precision; reveal more at dusk and dawn with more color trueness; and offer unparalleled edge-to-edge image quality and resolution.

So, until others are made like ours, only Zeiss will be guaranteed for life.

# The Alien Strategy

*Not all parasites trust to luck*

**by Milton Love**

I was perhaps ten years old when I saw *Invasion of the Body Snatchers.* Sitting in the darkened theater, greedily ingesting copious quantities of taffy and caramels, I watched spellbound as aliens from outer space took control of human bodies. Young sophisticate that I was, the film's impression on me was sufficiently profound that I spent most of that year sleeping with a night light.

Art being but a poor reflection of nature, it is not surprising that some organisms practice their own form of "body snatching"—entering a host and shaping host behavior to their own needs.

The lot of most parasites is not a happy one. The chances are remote that any single individual will survive to reproduce because in many species, the parasite must pass through one, two, or three intermediate hosts before landing in the "definitive" host, the one in which it attains mature form. And many parasite larvae are passive guests, trusting to chance that they will be passed from host to host.

To overcome these long odds, many species follow Gen. Nathan Bedford Forrest's advice on how to win battles: "Git thar fustest with the mostest" (there is evidence that he phrased this somewhat more grammatically). A female human roundworm, *Ascaris lumbricoides*, for instance, may produce as many as 200,000 eggs per day, flooding the environment with progeny.

Some parasites have opted for a different strategy: they alter the normal behavior of their hosts so as to increase their chances of transmission to other organisms. An example is the sheep liver trematode, *Dicrocoelium dendriticum.* Although a sheep is the definitive host, intermediate ones through which the worm must pass are a snail and an ant. Since ants do not form the bulk of a sheep's diet, the problem would be to increase the opportunity for sheep to accidentally swallow infected ant hosts. We might expect there to be any number of frustrated sheep liver trematodes frittering away their golden years inside ants.

In fact, the worm overcomes this dilemma by burrowing into the ant's brain and forcing it to behave so as to optimize the chances of its being ingested by a sheep. Normal behavior for an uninfected ant is to be active on the soil surface during the cool mornings and afternoons, retreating to burrows during midday, when higher temperatures might be detrimental. A parasitized ant, however, climbs up to the top of a grass blade during morning hours, clamps its jaws into the blade, and becomes immobile. As midday temperatures rise, the ant retreats down the blade, only to return in the cooler afternoon.

This is an elegant relationship indeed. The ant's (and the parasite's) chances of being eaten by sheep are increased, but the host's midday retreat is still allowed, insuring that the host will survive the higher temperatures and repeat the behavior if necessary.

Other parasites make their hosts more available to their usual predators. *Brachylecithum mosquensis*, a trematode found in robin livers, breaks down the antipredator mechanisms of its intermediate host, the carpenter ant. Although normally small, reclusive, photophobic animals, when infected, carpenter ants are quite obese and remain out and visible—slowly circling or remaining immobile for one or two hours. Infected hosts are also more active during cooler hours when the birds feed.

In these two cases, the parasites invade the brains of their hosts, but this is not always necessary to alter behavior. The tapeworm *Ligula intestinalis* infects the body cavity of its intermediate host, small fish such as sticklebacks, and the gut of its definitive host, fish-eating birds. The worm larva fills up much of the fish's body cavity, and the belly distends markedly, apparently causing great stress. Infected fish are more sluggish, less apt to join schools, and more likely to swim near the surface. This behavior and their increased size make infected fish more visible and available to fish-eating birds.

In at least one relationship, a parasite behaves so that only part of its host is eaten. Snails are the intermediate hosts of *Leucochloridium macrostomum*, a trematode utilizing songbirds as its definitive host. After entering the snail and undergoing a number of morphological changes, the worm larvae migrate to the snail's tentacles. Once in place, the larvae swell enormously, becoming bright green with yellow brown rings. As the infected tentacles expand and become transparent, they reveal the multihued parasite within. At this point, the normally shadow-dwelling snails become attracted by light and the parasite begins to pulse at forty to seventy beats per minute, causing the tentacles to vibrate. Attracted to what appear to be brightly colored, swaying insects, the songbirds pluck off the snail's tentacles, complete with the undoubtedly smug parasite.

Transmission of parasites does not always depend on hosts being eaten. Here too, some parasites increase their chances of survival.

*Sphaerularia bombi* is a nematode that infects queen bumblebees. In late summer and fall the queens burrow into soil banks and hibernate. There they are infected with adult female nematodes. Once inside the queens, the females produce larvae, which eventually take control of the bees. Instead of making burrows when the next hibernation season arrives, infected bees fly about continually and dig small soil depressions into which they deposit nematode larvae. The infected queens die soon afterward,

# Great ideas last forever

Great inventions have the power to forever change the past.

Victor Hasselblad changed the face of photography forever with the invention of the Hasselblad fully interchangeable camera system.

Never before and never since has there been a camera system to equal the Hasselblad–the *standard* of versatility and quality around the world. That's why Hasselblad is the overwhelming choice of professionals in every area of photography, from fashion to photo-journalism.

At the heart of the Hasselblad System is the 500C/M, with its interchangeable lenses, film magazines, viewfinders and film winder. The possibilities for adapting this basic camera to your own purposes are limitless: 22 different lenses, 7 film magazines, 8 viewfinders, 3 winding devices, 4 focusing screens, and a vast array of specialized accessories.

The Hasselblad 500C/M is easily held in the palm of your hand, yet it gives you the quality advantage of its large $2^1/_4 \times 2^1/_4$ negative size.

The Hasselblad System has made a profound contribution to photography. It could make a profound difference to you. For a luxurious folder, write to:

HASSELBLAD®

# Speak French like a diplomat!

What sort of people need to learn a foreign language as quickly and effectively as possible? *Foreign service personnel*, that's who. Members of America's diplomatic corps are assigned to U.S. embassies abroad, where they must be able to converse fluently in every situation.

Now *you* can make a start on learning to speak French just as these diplomatic personnel do—with the Foreign Service Institute's Basic French Course.

The U.S. Department of State has spent tens of thousands of dollars developing this course. It's by far *the most effective way* to learn French at your convenience and at your own pace.

The Basic French Course consists of a series of audio cassettes and an accompanying textbook. You simply follow the spoken and written instructions, listening and repeating. By the end of the course you'll find yourself learning and speaking entirely in French!

*This course turns your cassette player into a "teaching machine."* With its unique "pattern drill" learning method, you set your own pace—testing yourself, correcting errors, reinforcing accurate responses.

The FSI's Introductory Basic French Course comes in two parts. Part A provides an introduction to the simpler forms of the language plus a basic vocabulary. Part B introduces more complex structures and additional vocabulary.

You may order one or both parts of the Basic French Course:

☐ Basic French, Part A. 11 cassettes (16 hours) and 200-page text, $115.

☐ Basic French, Part B. 18 cassettes (25½ hours) and 300-page text, $149.

(New York State residents add sales tax)

Your cassettes are shipped to you in handsome library binders.

**TO ORDER, JUST CLIP THIS AD and mail it with your name and address and a check or money order.** Or, charge to your credit card (American Express, VISA, Master Charge, Diners Club) by enclosing card number, expiration date, and your signature.

The Foreign Service Institute's French course is *unconditionally guaranteed*. Try it for three weeks. If you're not convinced it's *the fastest, easiest, most painless way to learn French*, return it and we'll refund every penny you paid! Order today!

Many other FSI language courses also available. Write us.

# UNUSUAL.

That's the ideal description of the regal island country of Sri Lanka, once known as Ceylon. It's a fabulous spectacle. Whether you're looking at our ancient cities, wondrous wildlife or miles of beaches. The ultimate is our festival of the August moon. Located in the Jasmine-scented, mountain city of Kandy, you will feast your eyes on a thousand whirling dancers, a hundred costumed elephants, and more drummers than you've ever seen. The torchlight acrobatics of this 2,000 year old Perahera will, in just a few days, leave you with a lifetime of memories.

We have an unusual variety of tours – 75 in all – ranging from 3 to 21 days. The prices? Unusually low! Accomodations begin at $5. Deluxe sells for $45.

Sri Lanka is a most unusual warm weather vacation or convention spot. Only one hour from India, three hours from Katmandu, Bangkok and Singapore. Write for a color folder and tour digest that includes special airfare.

sri Lanka
*Pearl of the Indian Ocean.*

while the larval worms mature, males and females mate, and the fertilized female worms lie in readiness for unparasitized queen bees.

Shaping host behavior is not the only mechanism by which a parasite may increase its survival or reproductive potential.

Intriguing examples include the so-called parasitic castrators, organisms that sterilize their hosts, either directly (the parasite living within the gonads and destroying reproductive tissue) or indirectly (producing or stimulating the host to produce substances that lead to sterilization). Many parasites, including dinoflagellates, ciliates, trematodes, tapeworms, and copepods, have been implicated in this strategy.

The barnacle *Sacculina* is a dramatic case in point. Emitted into the water as a planktonic larva, the barnacle attaches itself to a crab. The barnacle larva degenerates into a mass of relatively undifferentiated tissue and flows through a dartlike tube thrust into the host. These cells are carried by the host circulatory system to the gut, where they multiply, forming an intricately branching network that soon spreads throughout the body. The denouement is that the host may not mature sexually, reproduce, or molt.

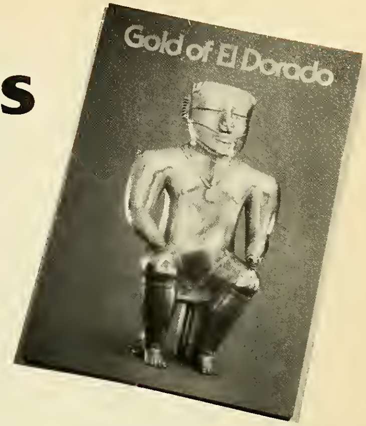
The benefits of host castration to the parasite are not always apparent and, indeed, in many cases may not exist. In several instances, however, it is possible to postulate advantages accruing to the parasite. There is some evidence that castrated hosts live longer and grow larger, perhaps because energy that might normally go toward reproduction can be utilized for tissue building, antibody production, and so on. For the parasite this could mean a longer reproductive life (because the host lives longer) and greater fecundity (often directly correlated with host size).

It would be dramatic to end this discussion by reporting that parasites (in the manner of *Brachylecithum*) influence human behavior—that, for instance, the larval stage of a bear parasite can cause humans to spread themselves with honey and hurl their bodies in front of astonished (and delighted) bruins. But there are no such parasites.

Now, if I were just sure of that, I could turn off my night light.

*Milton Love is a research associate in the Department of Biology at Occidental College, Los Angeles.*

# An Art Book That Took Centuries To Create



It took the American Museum of Natural History four years to arrange its exceptional exhibition of more than 500 pieces of ancient gold from Colombia. But those few years are a brief time when compared with the decades archeologists have spent digging (literally!) and studying the gold artifacts from tombs, caves, and buried sites. And all that time is short when compared with the many centuries prehistoric Indians practiced their craftsmanship and artistry to create these treasures.

So when it became the United States sponsor for this outstanding collection, the American Museum faced a dilemma. Could we do justice to all this effort and scholarship and beauty? We think we have. First, by dramatically displaying *Gold of El Dorado: The Heritage of Colombia* in one of our largest halls. The glowing reports from visitors tell us our efforts have been worthwhile. If you don't have a chance to see the show for yourself in New York, we hope you will see it in Chicago, San Francisco, or New Orleans on its year and a half tour.

The second challenge for the American Museum was the creation of an appropriate book to accompany the exhibition. We decided against a traditional catalog; against a small, boring volume with tiny black-and-white pictures that could never do justice to these fine objects. Instead, we decided to present a select number of the finest pieces of pre-Columbian gold in a large, stunning format. And to represent the three important elements that make a great art book we chose outstanding professionals.

First, photographer Lee Boltin. One of the greatest photographers of art objects, he also took the famous pictures of the Tutankhamun show. We sent him abroad to find and record great pieces of pre-Columbian art.

Second, archeologist Warwick Bray, from the University of London. One of the world's foremost authorities on pre-Columbian art, Bray is also a skilled writer, able to present fascinating background in a succinct, readable essay in the book. Dr. Bray organized the Colombian gold exhibition in London.

Third, Harry N. Abrams, Inc., America's leading publisher of fine art books. In a co-publishing venture with the American Museum, Abrams designed the book, supervised the preparation of 30 large color plates, and monitored the fine-quality printing.

The result is an unprecedented exhibition book. It is bold and big—each plate is 16 by 11½ inches—bigger than this magazine *opened up*. The paper is heavier than most posters. In fact, many persons have purchased two copies of the book in order to have one set of these fine art prints for framing.

And now for the happy ending. Because the Museum is a co-publisher, we are able to offer this soft-bound art book at a major savings from its normal retail price of $12.50. We are pleased to offer *Gold of El Dorado* to subscribers for only $8.95—a 28% savings off its regular price. This special offer is valid only during the exhibition and only while our limited supply lasts. We suggest that you order one or more copies immediately. Of course, if you are not satisfied after you have had an opportunity to examine it in your home, simply return the book and the Museum will refund the purchase price.

**Natural History Books**

**Gold of El Dorado Book**

# Horse and Buggy Island

*This renowned Michigan resort fought its dung-breeding flies with pesticides until a new insect plague emerged*

**by M. Keith Kennedy and Richard W. Merritt**

Mackinac Island, one of the oldest and most famous tourist attractions in Michigan, nestles between the Upper and Lower Peninsulas where the waters of Lake Huron and Lake Michigan meet to form the Straits of Mackinac. The island was well known to Indians and early explorers more than 300 years ago, and its strategic importance was recognized by the British, who, in 1779, established Fort Mackinac to protect English fur traders from American troops during the Revolutionary War. For the past 200 years, however, it has been the island's scenic beauty that has lured such famous tourists as William Cullen Bryant, Harry S. Truman, John F. Kennedy, and Gerald R. Ford.

In addition to scenery, Mackinac Island has a unique feature that helps to attract over 750,000 visitors a year —horse-drawn carriages are a major means of transportation on the island. No automobiles are allowed. Tourists take guided carriage and horse tours, pedal around on rented bicycles, and take walks along numerous trails. The famous Mackinac Island fudge provides an additional attraction, and local islanders commonly refer to the thousands of tourists who descend daily on the island during the summer as "fudgies."

The island's decidedly turn-of-the-century atmosphere is due to its Victorian architecture and horse-filled streets. But the maintenance of this atmosphere is not without drawbacks. The approximately 500 to 600 horses needed each summer to meet the transportation needs of the increasing number of visitors produce an enormous amount of manure. The manure, in turn, provides breeding sites for two nasty pests, the housefly (*Musca domestica*) and the biting stable fly (*Stomoxys calcitrans*). These flies typically breed in disturbed manure that has been mixed with straw and urine, which in most instances occurs in and around stables and adjacent barns. Despite efforts to dispose of the manure, enough has persisted in recent years to allow the development of intolerable numbers of flies.

Houseflies are more than a simple nuisance to fudge shops and storekeepers. Annual outbreaks of dysentery were once common on Mackinac Island, and public health officials believed the excessive housefly population was a contributing factor. At one time, many of the island's residents used cooking utensils fitted with specially designed fly screens or cages to keep these ubiquitous pests from contaminating food during cooking and dining.

Stable flies also pose a serious problem because of their vicious biting habit. Carriage horses frequently become skittish from numerous bites, and humans are often targets for hungry stable flies.

Both fly species were a part of nineteenth-century life, especially in towns with large concentrations of horses. But filth fly problems, not an appetizing topic, are rarely mentioned in descriptions of American frontier life. How many Westerns have shown John Wayne, Roy Rogers, or Gene Autry fighting off flies in the local saloon?

Despite their lack of historical recognition, dung-breeding pestiferous flies are a potential problem wherever large numbers of livestock are kept in small areas. Prior to 1945, sanitation was the major method recommended for fly control on Mackinac Island. Unfortunately, many livery owners devoted most of their time to the tourist trade and made few efforts to haul manure regularly from stables to the island landfill for disposal. Manure was frequently piled in alleys or dumped inconspicuously along roadsides. Sanitation was often neglected by many who were convinced that it was a waste of time.

In the summer of 1945, the national conference of state governors was scheduled to be held at the island's famous Grand Hotel. This created an urgent need for a fly-free environment. At precisely this time the U.S. Army released the insecticide DDT for experimental civilian use, and a project was quickly developed to test DDT sprays as a potential fly-control method on Mackinac Island.

The project was an immediate success, providing "astonishing" fly control, according to islanders and public health officials. The mayor of Mackinac Island was so impressed with the new "miracle drug" that he set fire to several hundred fly traps at a special ceremony to usher in a new era of chemical warfare against flies. The pesticide treadmill had begun to roll.

DDT was used for fly control until late in 1949 when the fly population showed high levels of resistance to the chemical. This was one of the first documented cases of insect resistance to DDT in the United States. For the next five years, other chemically similar substances, such as methoxychlor, chlordane, lindane, and dieldrin, were used in various combinations with DDT with unsatisfactory results because the flies also developed resistance to these pesticides. Malathion, one of the second generation of chemical pesticides and a common component of widely available house

M. Keith Kennedy

CITY

Courtesy Michigan Travel Bureau

and garden sprays, then came into use. It was used until 1964, when resistance again became a problem. From 1964 until 1977, Cygon (dimethoate), which is in the same chemical group as Malathion, was used exclusively. It was applied with a mist blower every three to four days during the summer.

In 1978, Mackinac Island houseflies tested at the USDA Insects Affecting Man Laboratory in Gainesville, Florida, proved to be five times more resistant to Cygon than a laboratory strain known to be resistant to several other pesticides. Upon hearing this news, the islanders promptly began referring to the two-winged pests as "superflies."

In the past few years, a second serious insect problem developed on the island: an outbreak of the European fruit lecanium scale (*Lecanium corni* complex) that seriously affected many of the shade and fruit trees in the city and in Mackinac Island State Park. In its adult, immobile stage, the lecanium scale (about the size of a large ladybug) uses its sucking mouthparts to draw nutrients out of the tree. The scale's hard, waxy covering protects it from most liquid insecticides.

Trees infested with large numbers of scale lost branches and suffered a general decline in vigor. Plum trees, a favorite host of the scale, were especially hard hit. In the early 1940s, plums were extensively planted on the island, and Mackinac plum jams and preserves became popular in the local area. The scale, once a devastating plum pest in Eastern Europe, appears to have contributed to the plum decline on Mackinac Island during the last twenty to thirty years. Today, most of Mackinac's few remaining plum trees are in poor shape, suffering from the scale and from black knot, a fungal disease.

*Mackinac Island, which lies between Lakes Huron and Michigan, has lured tourists for 200 years. Cars are banned on the island, and visitors walk, ride bicycles, or use the ubiquitous horse-drawn carriages.*

The scale problem, not the flies, prompted the state park personnel to call us in. Normally, lecanium scale is kept at low densities by numerous parasites and predators, but in their absence, scale can quickly increase to damaging levels. Did something on Mackinac Island eliminate or reduce the scale's natural enemies? We asked ourselves this question when first confronted with the problem. After a preliminary investigation of the island's fly-control program, the answer became apparent. The Cygon spray operators routinely directed the mist blower spray into the lower canopies of trees along the control routes in the city and in the state park. A quick check showed that all the scale-infested trees were on or near this route. The scale's natural enemies were being effectively eliminated by the Cygon spray, while the scale itself, susceptible only to dormant oil sprays or applications directed at its crawler stage, was not affected. Released from its natural controls, the lecanium scale in-

ORNS LIQUOR
PIZZA

M. Keith Kennedy

creased to outbreak levels. The control program directed at a primary pest (pestiferous flies) had induced an outbreak of a secondary, previously unimportant pest, the lecanium scale.

But apart from the scale outbreak, the control program was in trouble. The island was slowly losing its chemical war against flies. The bulging arsenal of new insecticides that existed in the fifties and early sixties was no longer available by the late seventies, and the effectiveness of any new chemical was quickly compromised by the flies' ability to develop resistance. Fly control on the island had reached a point where alternatives to the current program had to be considered if satisfactory results were to be obtained without further upsetting the island's ecological balance.

The city council and the Mackinac Island State Park Commission, which maintains Fort Mackinac and approximately 80 percent of the island's 2,465 acres, jointly sponsored the fly-control program. In 1977, we proposed to these organizations that a new fly-management system be considered. Our proposal emphasized an integrated approach using selected cultural, chemical, and biological control techniques instead of a single control method. We placed the primary emphasis on sanitation—prompt and effective disposal of manure from stables and other potential fly-breeding areas.

Our proposal did not go unchallenged. For over thirty years, residents and seasonal shopkeepers had relied totally on insecticides. Spraying was a relatively low-cost, minimal-labor control method that required little knowledge, cooperation, or energy expenditure by individuals. In addition, many summer residents and local businessmen were interested only in short-term fly-control efforts, and any control program extending beyond Labor Day was of little interest to them. A strict sanitation program placed responsibility with individual residents and businessmen. "The trouble with sanitation is that it might not get done," one of the city councilmen said at a town meeting. "An effective sanitation program would require the city to hire personnel to enforce the sanitation regulations," he said, while chemical control was "like a great big policeman." The councilman was right: a sanitation program required the enforcement of existing or future ordi-

Richard W Merritt

*Part of the island's new pest-control program was to improve sanitation in stables and corrals. Both the stable fly, above, and the housefly breed in the disturbed manure found in these areas.*

nances, as well as cooperation between city and state park personnel and understanding from residents and business persons.

After much discussion, the city council and the state park commission voted to support our program for a one-year trial period. The money previously spent for insecticides and a spray crew was to be used to fund the new, integrated fly-management program in 1978.

We shortly discovered that the islanders generally did not understand where the flies came from or where they were going. The adult fly had been the nuisance stage and the major target for years, and there was little interest in the immature stages or knowledge of where they occurred. The local newspaper reported that one city council member was concerned that the city might be paying Michigan State University personnel to control pests that lived on property owned by the state parks. Our dispersal studies used dye-marked stable flies to show that adult flies were moving freely throughout the island with little concern for property rights. An education program was initiated through newspaper stories, word of mouth, and a short documentary movie, shown at council meetings, that concentrated on the life history (breeding sites, dispersal habits, and so on) of the flies. Once they understood that the major breeding area of houseflies and stable flies was disturbed manure, the residents were more easily convinced that sanitation measures would reduce the adult fly population, and the program received increased support.

In the spring of 1978, we initiated a field study on Mackinac Island to determine adult population densities and major larval breeding sites of the housefly and stable fly. This information was necessary to concentrate control efforts where fly breeding was heaviest and to evaluate the effects of the integrated control program after implementation.

We determined the major larval breeding sites by closely examining horse manure piles, droppings, and organic wastes in and around corrals, stables, feed-storage areas, feeding troughs, and garbage cans and other waste receptacles. In cooperation with Richard Patterson, of the Insects Affecting Man Laboratory, we sampled adult stable fly populations by placing fiberglass panels coated with a sticky material at major breeding sites. The fiberglass panel reflects ultraviolet light in such a way that large numbers of adult stable flies are attracted to it, and the sticky material traps them. These traps have proved extremely effective in providing accurate indexes of adult densities in the field and can also serve as a control device if the panels are treated with an insecticide (for example, Permethrin) instead of an adhesive material. USDA studies have shown that in seven to eight days this method can successfully reduce local stable fly populations around barns by 84 to 90 percent. Because houseflies are not attracted to the fiberglass panels, we used other types of traps containing commercial housefly baits for them.

We also planned to release two species of tiny parasitic wasps, *Muscidifurax raptor* and *Spalangia endius*, to evaluate their potential for controlling flies on the island. Both wasp species attack the pupal stage of the fly, killing the larvae and preventing adult emergence. Just when we felt the program was gaining general acceptance, the local newspaper carried an article entitled "Tiny Wasps Could Replace Insecticides in Combating Flies." This

John Gadia/fpg

*The island's architecture and old-fashioned transportation provide a turn-of-the-century atmosphere. Scouts on the march, facing page, confront another aspect of life before the advent of the motorcar.*

alarmed many residents because they associated wasps with yellow jackets or hornets. Although the wasps involved were small (less than a millimeter long), solitary parasites that attacked only fly pupae, we were often questioned about the size of the wasps or their nest and how injurious the sting was to humans. City and park officials asked if we would need additional money to control the wasps once they controlled the flies. From that time on we referred to the wasps as parasites and emphasized them less than other control measures.

In addition to searching for larval breeding areas and monitoring adult fly population densities, we tested several other control methods on a trial basis. Using a pyrethroid insecticide, we tried localized spraying of major adult fly resting sites, such as sides of stables and manure wagons. Pyrethroids are synthetic versions of pyrethrins, naturally occurring insecticides produced by chrysanthemums and other plants. We did this sort of spraying only in emergencies when adult fly populations reached outbreak proportions.

We also recommended the following sanitation measures to stable and store owners: cleaning manure from barns and stables on a weekly basis; removing fallen feed from cracks in horse stalls and adding rock salt or lime to these sites to prevent larval development; covering all trash cans; providing flyproof screens for store windows and doors; laying a cement floor where manure wagons were parked to eliminate breeding areas and facilitate cleanup; and composting manure to prevent larval and pupal development. Finally we conducted a public opinion survey on the island to better understand reactions of tourists and residents to pest fly problems.

By the end of summer 1978, we had learned a great deal about the fly and people communities on Mackinac Island. We had located and mapped major breeding areas for fly larvae and major adult resting sites. We discovered who was contributing to the fly problem through poor sanitary practices and who was willing to cooperate with the program. Our public opinion survey showed that flies were not as serious a problem to tourists as they were to residents. Of 1,000 tourists surveyed, only one said that the flies would keep him/her from visiting the island again.

Ed Gersabeck, a graduate student who was working with us, established a rapport with many of the islanders and state park and city personnel. He became known variously as the Bug Man or Lord of the Flies, and as the Dear Abby of the island for problems ranging from how to get rid of mosquitoes, horseflies, and no-see-ums (small, biting gnats) to how to kill the bats that lived in the governor's summer house. To date, we are still trying to convince some of the island residents that our role is not that of general exterminator. However, as a result of our initial integrated control attempts during the first year, adult stable fly densities in selected areas declined 25 percent, and the amount of Cygon insecticide applied was reduced from 235 gallons to less than one. Because of this initial success, we were funded for an additional year.

We expanded our pilot control program to the entire island in 1979, using sanitary measures, poison panel traps, localized spraying, and parasite releases. The results were significant: we achieved a 40 to 50 percent decrease in the adult stable fly population throughout the island; housefly populations declined by an estimated 25 to 30 percent. On a larger scale, we completely eliminated the broad area insecticide spray program, which in turn reduced environmental contamination. In addition, we initiated and supported the passage of a strong ordinance that would impose fines on those not complying with established sanitation measures.

The discontinuance of the insecticide fogging was not without negative consequences, however. During 1978–79, there were apparent increases in yellow jacket, mosquito, and horsefly populations, as well as an increase in the lilac leaf miner. These increases, observed mainly by island residents, suggest the nonspecificity of the previous control program.

At the present time, we plan to continue the integrated fly-management program on Mackinac Island this summer. The most important job ahead is training city and state park personnel to take over the program when our involvement ends. The program requires their total cooperation, as well as that of summer residents and businessmen.

The serious ecological problems that resulted from the original chemical control program—increased insecticide resistance in a pest population (housefly and stable fly) and a secondary pest outbreak (lecanium scale)—are not unique to Mackinac Island. In the late 1960s, an intensive insecticide control program for mosquitoes in the California-Nevada resort area of Lake Tahoe led to an outbreak of pine needle scale (*Chionaspis pinifoliae*). More recently lecanium scale outbreaks have occurred in two Michigan cities that regularly fogged their streets with insecticide for mosquito control.

The failure to consider the effects of pest-control strategies on the total ecosystem led to serious consequences in all these situations. As we have demonstrated, however, the use of an integrated pest management approach can provide effective control and is more compatible with our natural environment. ☐

# Dirty River Turtles

*That Illinois River has its silt,*
*has its sewage, has its turbid waters,*
*but those old turtles just keep rolling along*

### by Don Moll

The Illinois River is comparable to a fine old painting—both are easier to admire from a distance. From the heights of Peoria's Grandview Drive, the river appears as a broad silver band of tranquil beauty, coiling through patches of forest and cultivated fields in great serpentine loops on its slow journey to meet the Mississippi, nearly 175 miles to the south. Drop down from the bluff and stand on the riverbank at Waterworks Park and the idyllic image is quickly shattered by the odor from the bloated bodies of carp and gar washing against the shore. They move on thick, oily green water in rhythm to the backwash tides generated by the barge and motorboat traffic moving continually through the narrow channel. No rooted aquatic vegetation is visible and the only birds in view are grackles and ring-billed gulls, garbage eaters working the bodies along the shore. The Illinois River has not always been so, but unlike the paintings of the old masters, the river has not aged well.

When Pere Marquette first traveled the Illinois Valley in 1673 he wrote, "We have seen nothing like this river that we enter, as regards to its fertility of soil, its prairies and woods; its cattle, elk, deer, wildcats, bustards, swans, ducks, parroquets, and even beaver." Capt. Howard Stansbury, in 1838, described the valley as "one to

James P. Rowan

*The polluted Illinois River flows past Starved Rock State Park near Utica. Smooth soft-shelled turtles, left, have declined in the river because silt has covered the sand bars they need for nesting.*

Werdene Wieser

five miles wide, deeply overflowed in every freshet, filled with bayous, ponds, and swamps, and infested with wild beasts." Throughout the nineteenth and early twentieth century conditions were only little changed from these early descriptions of most of the river and adjacent flood plain. The region was a richly vegetated fish and wildlife paradise, famed for its bass fishing and waterfowl hunting. Weekend trains known as fisherman's specials hauled in carloads of anglers to sample the river's richness, and a diverse array of sportsmen, including President Benjamin Harrison and the gangster Al Capone, shot duck from its shores. A booming mussel fishery supplied pearls and shells for buttons, while commercial fishing provided tons of fish for the markets of Chicago and the cities of the eastern seaboard.

Turtle fishing was also big business at the turn of the century, and an all-time high catch of 547,000 pounds, based mainly on snapping and soft-shelled turtles, was recorded for 1899. The first reference, in 1892, to the quality of the Illinois River as a turtle habitat was given by the naturalist Harrison Garman in a comprehensive synopsis of the reptiles and amphibians known from the state at that time. His judgment of the river's excellence was based on the large number of turtles observed, the extensive sloughs, the numerous sandy shores suitable for nesting, and the ample animal and vegetable life, which provided food and shelter for the resident turtles. Alvin Cahn, author of *The Turtles of Illinois* (1937), remarked similarly that the river's favorable environment of slow-moving water, swampy flood plain lakes, and abundant, sheltering vegetation was responsible for its very large turtle population.

Inevitably though, as the human population of Illinois expanded during the late nineteenth century, the river was increasingly subjected to the pressures imposed by the developing cities along its banks and the clearing and draining of its fertile flood plain for agricultural use. The northern part of the river changed rapidly into an open sewer as Chicago grew and flushed its sewage and stockyard wastes into the Illinois River via one of its tributaries, the Des Plaines. To accomplish this, special canals were constructed, and in 1871, the Chicago River's flow was reversed to carry wastes away from Lake Michigan—the source of Chicago's drinking water—and into the Illinois River system. The resultant effluent flow killed and bloated river fish by the ton, and in a reference indicative of the pollution tolerance of many turtles, albeit with a somewhat uncomplimentary ring to it, E. W. Nelson noted: "In July and August when the water is worst even the mud turtles leave the river in disgust and seek less odorous homes" (Report of the U.S. Commissioner of Fish and Fisheries for 1875–1876).

During the first two decades of the twentieth century the upper hundred miles of the river became practically anaerobic and nearly fishless. In the late summer of 1912, a vertebrate survey near Morris yielded only a few fungused bullheads, a frog, two snapping turtles, and a soft-shelled turtle in water described the year before as emitting foul privy odors and carrying floating, pan-sized, putrescent masses of soft, slimy matter borne up by gases from beneath. The central and lower stretches of the river remained relatively unaffected by these problems, and with improved sewage treatment techniques and regulations, the condition of the upper river improved dramatically. The major destroyer of the old river ecosystem has been a seemingly benign substance—silt.

The slow-flowing Illinois has always had some trouble carrying its load of suspended soil particles. With increased clearing and drainage of flood plain forests and wetlands in exchange for more row crop acreage, an important buffer between the river and proportionately increasing soil runoff has been lost. Channelization of feeder tributaries, urban storm runoff, and flooding of adjacent bare agricultural land during high-water periods have caused a tremendous increase in the suspended soil load of the river. An ex-

Tom Stack and Associates

*Sewage and industrial wastes pouring into the river have depleted oxygen levels. Severe fish kills have resulted, providing abundant food for such turtles as the common snapping turtle.*

tensive lock and dam system has further reduced the silt-carrying capacity of the river by slowing its already sluggish rate of flow, while heavy barge and boat traffic and large bottom-roiling populations of introduced carp function synergistically to keep the river in a constant state of turbid flux.

Not surprisingly, the drastic changes in the river environment have caused great and largely unwelcome changes in the composition and structure of its biota during the span of a turtle's lifetime. Rooted aquatic vegetation has been nearly eliminated from the river and adjacent lakes, and the once rich macroinvertebrate, fish, and seasonal waterfowl faunas have declined accordingly in numbers and condition or have been replaced entirely by more pollution-tolerant forms. The industries dependent upon these populations have crashed with them. Commercial turtling declined as the economic value of the catch fell, and commercial fishermen, the main turtle catchers, looked elsewhere for employment after the fin fishery also sagged.

If by any stretch of the imagination a silver lining can be found in this dark picture, it would have to be based on the remarkably detailed documentation—by aquatic biologists of the Illinois Natural History Survey and its predecessor, the State Laboratory of Natural History—of the changes that have occurred over the last hundred years. From the 1870s to the present day, a distinguished chain of workers—Stephen Forbes, Carl Kofoid, Robert Richardson, William Starrett, Philip Smith, Frank Bellrose, and many others—have watched and recorded in unparalleled detail the demise of the river and its biota, earning the Illinois its title as the "most studied" river in the world. One of the few gaps in this documentation has been the effect of habitat alteration on the ecology of the river's turtle fauna.

Having grown up along the banks of the Illinois River, and from early on a student of turtles and local natural history, I became intrigued by this gap in turtle knowledge and began to search for clues. Cahn's 1937 work was a mine of information on the natural history of Illinois River turtles in the relatively unpolluted period of the early twentieth century, and Phil Smith's treatise on the amphibians and reptiles of Illinois in 1961 gave important distributional information. Largely lacking, however, was published ecological information from the transitional period to the badly polluted modern condition, and on the status and ecology of the present turtle fauna. To solve the former problem, I became a skulker in museum basements, private collections, and the musty storage closets of the Illinois Natural History Survey and other agencies, where specimens, mice, and unpublished information of the old river biologists were housed. For the latter problem, I began trapping the turtles of the river and remaining flood plain lakes and wetlands. After several years of such investigations a relatively clear, and initially surprising, picture of the river's turtle populations during the critical period of change has emerged.

Despite drastic habitat modifications, my trapping campaign of the mid-1970s showed large, thriving populations of painted, red-eared, map, false map (now believed to be composed of at least two morphologically similar sibling species previously unrecognized), spiny soft-shelled, stinkpot, and common snapping turtles still inhabit the river, as they did in the days of Garman and Cahn. On a sunny spring day, logs and stumps near the banks are crowded with the common basking species, serenely unperturbed by the passing stream of river traffic and water skiers. The eastern mud turtle and the alligator snapping turtle, two species apparently always rare in the river, were not collected during my study, and although both may still turn up occasionally, their status remains uncertain.

Three species that were once surely abundant in the river or adjacent flood plain wetlands have weathered the modern changes badly. The smooth soft-shelled turtle and the Illinois mud turtle are probably gone from the modern river ecosystem. Both require extensive areas of clean sand—a habitat largely extirpated from the Illinois River by the choking layers of mud now deposited upon the once common sandy bars and bottoms along its course. Mike Plummer of Harding College found that smooth soft-shells in the Kansas River will not nest on sand bars, the principal nesting sites for this species, if they are covered by silt, even if they were used extensively before coverage. Egg clutches laid before coverage are doomed to failure, probably because the hard, sunbaked surface that develops prevents emergence of the hatchlings entombed be-

Tom Brakefield, Animals Animals

neath. The last museum specimens I could find of this species collected from the Illinois River system came from the lower river and from Chautauqua Lake in 1940, three years before the great spring floods of 1943 and 1944 dumped tons of silt into the river and adjacent lakes, drastically changing their ecological makeup. Unpublished records indicate that smooth soft-shells were present elsewhere in the river at least through 1942 and probably later.

Although unproved, similar factors are probably partly responsible for the decline of the Illinois mud turtle. Laboratory studies I have conducted indicate the mud turtle, more of a pond dweller than the smooth soft-shell, has great difficulty digging into any but loose, sandy substrates. The extensive drainage of the ponds and wetlands of the flood plain and adjacent sand prairies has undoubtedly been a major reason for the mud turtles' decline. David Thompson, the first collector of this turtle in Illinois, reported in the 1920s that he had seen twenty to twenty-five specimens along a ninety-mile stretch of river between Meredosia and Peoria; in 1931, eleven more specimens were collected at Meredosia Bay. I trapped the same stretch of river and the bay for this turtle regularly between 1971 and 1976 without success, but remnant populations still exist a few miles east of the river in semipermanent sand prairie ponds.

The Blanding's turtle, once common in river sloughs and wetlands, has been hurt by rising water levels from lock and dam construction in the thirties, which inundated large areas of flood plain marsh habitat, and by drainage of other remaining wetlands for increased row crop acreage. A few are still present here and there, their brilliant yellow throats making them easily visible when they take a breath at the water surface, but their populations are greatly diminished from those of the early days.

Why these populations declined seems fairly evident, at least qualitatively, but of equal or greater interest to me, and a happier subject to cogitate on, is how so many species have survived, and in such large numbers, the destruction of the old river environment. Even more surprising, analyses indicate that several species resident in the mucky river ecosystem of the 1970s are growing and reproduc-

Tom McHugh, Photo Researchers

ing at a faster rate than ever. Some detective work points to the reasons why.

There are no written records of turtle growth rates, and only incomplete reproductive data available from the nineteenth and early twentieth century period, to compare with the current data supplied by my trapping program. A properly preserved turtle, however, can yield a wealth of ecological information, and fortunately many such specimens are available in private collections and museums scattered throughout Illinois. Most were collected incidentally, beginning in the 1870s, during fish surveys by Illinois Natural History Survey biologists, but one particularly valuable group of specimens housed in the musty, plastic-vine-shrouded catacombs of the Chicago Academy of Sciences was collected in the course of state herpetological surveys by Francis Lueth and Phil Smith. Duly recorded and cataloged by location and date of capture, they remained largely untouched until I dug them out in 1976. Through a small incision in front of a hind leg, I could quickly remove the digestive and female reproductive tracts for later analysis, with no apparent damage to the specimen. Growth rings indelibly etched into the plastral shell scutes of many species can be used to calculate growth rates through application of simple formulas. With fragmentary dietary and reproductive data in the early literature and unpublished agency files, and our knowledge of the early river environment provided by INHS biologists, a clearer picture of turtle ecology in the early river and its changes through time emerges.

Turtle survival in the drastically changing conditions of the river and adjacent flood plain lakes during this century is basically a result of the turtle's longevity and its capacity for behavioral and physiological opportunism. Largely independent of aqueous oxygen levels, the turtles have not fallen victim to the modern river's chronic oxygen depletion, which has doomed many fish species. The dearth of rooted aquatic vegetation, once used extensively by the river's turtles for food and shelter, has evidently not affected them much either. The increased turbidity of the water may in part compensate for the lack of sheltering vegetation since a small submerged turtle is virtually invisible to any sight-hunting predator at a distance of only a few centimeters. Also, populations of turtle predators, such as largemouth bass, northern pike, great blue herons, and common egrets, have declined as water clarity was reduced. The loose soil of plowed fields, so abundant adjacent to the river, offers fine nesting areas for most turtle species, and only heavy egg predation by raccoons and skunks seriously limits the hatch.

Another key to the success of many of the turtle species is their ability to eat whatever the river provides. Large populations of maps, paints, sliders, stinkpots, and soft-shells thrive in areas of the river with no benthic macroinvertebrate fauna or rooted aquatic vegetation whatsoever. Drowned insects, bottom mud and detritus, and floating fish carrion make up the bulk of their diet. Many species that were highly herbivorous as adults in the old days are now strict carnivores and detritivores throughout life. Even the morphologically specialized map turtle, which has broad alveolar jaw surfaces for crushing mollusks (a main food source in the old river environment), seems to be doing well on an insect and carrion diet. High-water periods provide easy access to terrestrial vegetation, insects, and other normally inaccessible terrestrial fare. (During a high-water period on the Mississippi River, I collected a big female false map turtle stuffed with red-winged blackbird nestlings.) Fish kills caused

by low oxygen levels or severe winters occasionally provide feasts for turtles.

Of major importance to the turtles are localized irruptions of benthic, pollution-tolerant insect larvae populations. Populations of midge or caddis fly species appear regularly enough and in such tremendous density as to provide a reliable, highly nutritious diet for turtles. Once established, these benthic larval populations may be present over a period of years, but can fluctuate widely in density in different years or be eradicated completely for reasons not yet understood. Lake Chautauqua, for instance, had tremendous midge larvae populations in the early 1950s but is now nearly devoid of benthic insect larvae. The false map turtles of the Illinois River specialize in this food resource and are found only in areas where large benthic larvae populations exist. The highest turtle growth rates and reproductive potentials for several species were observed in specimens collected from such areas. Their digestive tracts were usually packed with larvae. Specimens collected from more barren areas usually had much lower growth and reproductive rates. Turtles I collected from Lake Chautauqua in the 1970s had grown more slowly and produced fewer, smaller egg clutches each year than did the available turtle specimens collected from this lake in the 1950s. For example, most painted turtles collected here between 1950 and 1951, when insect larvae were abundant, produced three clutches of about eleven eggs each per year, while specimens obtained from the barren lake of 1975–76 usually only produced one clutch of four to five eggs annually. Several of my other study areas also confirm this relationship of dietary quality with growth and reproductive success, first noted in papers by Whit Gibbons and Donald Tinkle concerning painted turtles of Michigan's badly polluted Kalamazoo River.

An additional food source for some Illinois River turtles has become available in recent years. Since 1970 a pollution-tolerant exotic mollusk, the Asian clam, *Corbicula manilensis,* has extended its range into the Illinois River and is becoming well established. Digestive tract analyses of map turtles from the lower river indicate that the Asian clam is being utilized as a food source and may replace the currently depauperate fingernail clam and snail populations that were once a staple of the map turtle's diet.

Although we can be thankful for this persistent remnant of the old river fauna, we obviously can take little credit for its continued existence. The resident turtles of the modern river exist there in spite of us. They have adapted to current conditions because of their flexibility and opportunism.

*The turbidity of the Illinois River, combined with its silt load, helps obscure immature turtles, such as this red-eared, from predators. This species is thriving in the river.*

Aesthetically, the modern river is a grotesque imitation, a travesty, of its former self, and I am greatly saddened that I can never see what Marquette or Forbes or even Cahn could take for granted.

But, strangely, the lure of the river is still there, and a love for the place is deeply ingrained in those of us who study it or fish it or who have long lived along its shores through the hell and high water to be found there. I believe this feeling for the river stems from our memories, whether first- or second-hand, of what it once was. The vestiges of the good old days may take the form of a pair of wood ducks startled from the riverbank brush or the occasional sauger or northern pike still hooked by river fishermen. For me, however, the sliders and maps lining the logs along the channels and sloughs on a hot, sunny spring day recall the lazy tranquility of the old river as nothing else can. The big old "red ears" sitting there have seen it all; they have watched the place change, and I wonder whether they will cope with the rest of the century as well as they did with what is already past. ☐

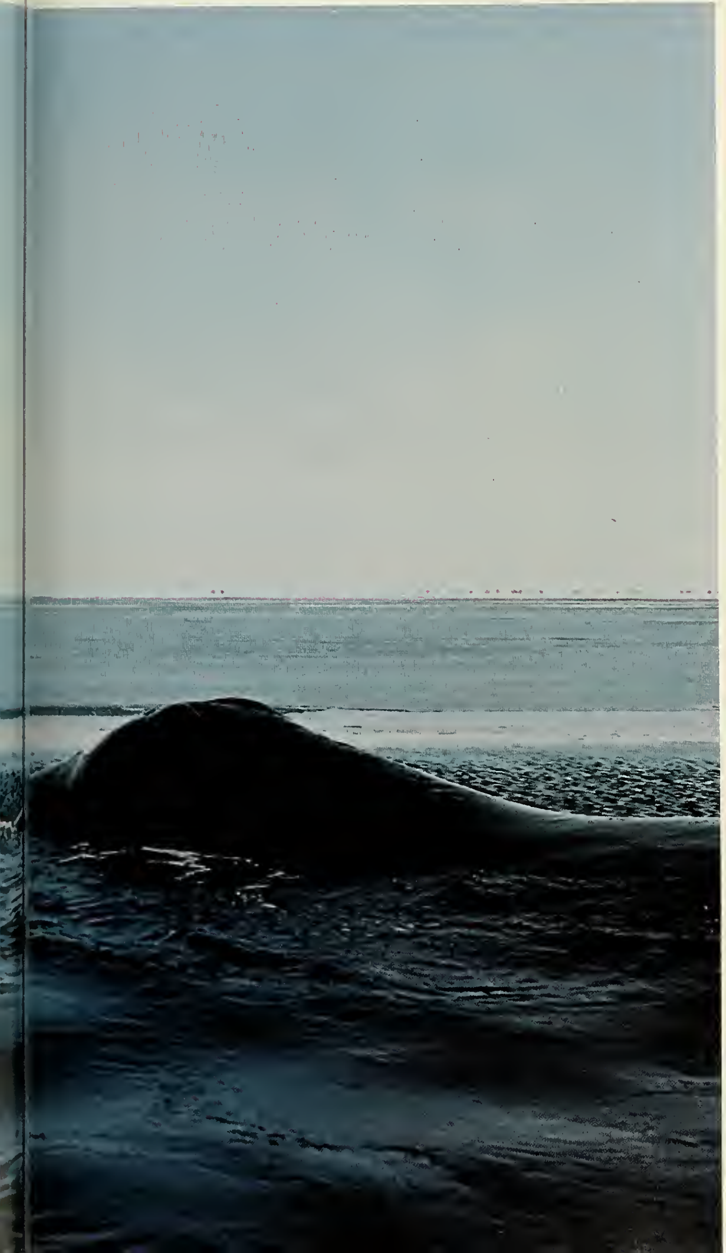
# Battle of the Bowheads

*The International Whaling Commission claims there are too few. The Eskimos contend there are enough. At stake is the survival of the whales and a culture*

### by John Bockstoce

Chlaus Lötscher



As he bent over the bow of his whaleboat, knocking the glistening ice from the harpoon line, Luke Koonook's face was expressionless. He ignored the 10 degree north wind that stabbed at his bare hands and worked his way aft along the gunwhale of the eighteen-foot sealskin-covered boat. Five or six of his sons and nephews joined him, and while they worked, I saw each one instinctively flick his eyes at the ink black ribbon of water that separated the shore-fast ice, on which we were standing, from the moving ice pack.

Their faces, too, were impassive in the fierce cold, showing a discipline born of years of arctic hunting; the only indication that they felt the cold at all was a slight change in their stance as they tapped one caribou-skin mukluk against the other, forcing the blood back into their feet.

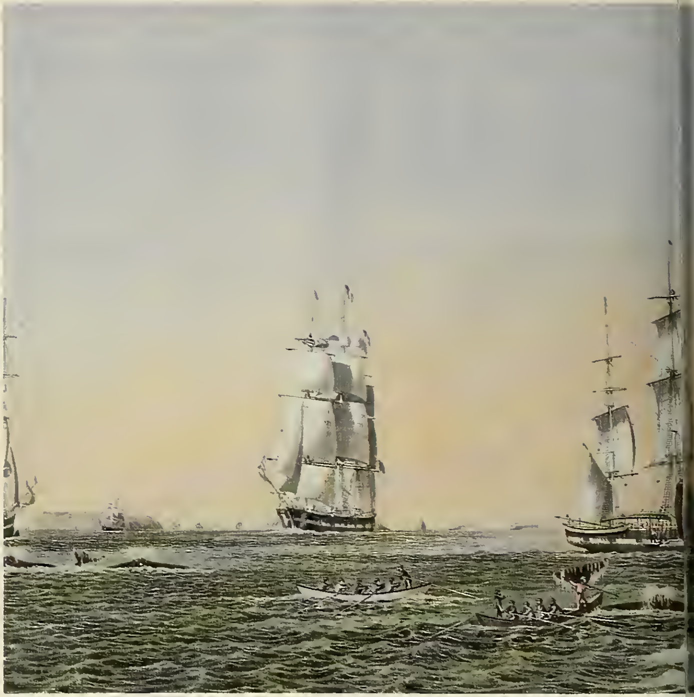
We were one of a dozen whaling crews stationed a mile offshore in the Chukchi Sea near Point Hope, Alaska, where the Eskimos spend two months of each spring waiting for the bowhead whales to swim past on their spring migration from the Bering to the Beaufort seas. The bowheads, some of them sixty feet long and weighing fifty tons or more, follow narrow cracks in the ice along the northwest coast of Alaska from the Bering Strait to Point Barrow. And it is in these waters that the Eskimos have gone whaling for a thousand years.

When the whaling gear was in order, Luke turned to me and brought up a subject we had discussed earlier; clearly, it had been on his mind during the intervening half hour. His eyes were bloodshot and red-rimmed from thirty-six sleepless hours spent paddling after several bowheads, and I could see he was deadly serious.

"If they stop us whaling, I don't know what we'll do. We have no other way of life. Point Hopers are whalers."

He was referring to the International Whaling Commission's (IWC) recommendation that Eskimo whaling should be stopped. Although the IWC

Hugo Poisson, The Kendall Whaling Museum



subsequently modified its stand to allow a small quota, Luke, like most Eskimos, saw the action as a direct threat to his way of life.

Norman Omnik, one of the crew, added, only half jokingly: "Whaling is our Christmas, Fourth of July, and Thanksgiving." He was right. The whale hunt not only provides the Eskimos with a vast amount of food but it is also deeply interwoven with their culture. Their celebration of whaling at important festivals throughout the year reaffirms their cultural unity and uniqueness, their kinship and other social ties, and their close, respectful, and finely balanced association with nature.

"The bowhead is the most endangered of whale species," Ray Gambell, the secretary of the IWC, told me recently. "Further Eskimo hunting could possibly result in the bowhead's extinction. . . . [the IWC] had to act in what it saw to be a desperate situation."

Thus, for the first time, the IWC, which regulates the catch of whales among member commercial whaling nations, has come into conflict with an aboriginal people. Since 1972 the IWC had been issuing increasingly urgent warnings about the Eskimo hunt, but the roots of the problem are far older, reaching back more than two hundred years.

The Eskimos began whaling in northwestern Alaska about A.D. 800. Their whaling developed from a constellation of factors, the most important among them being the acquisition of toggle-headed harpoons and inflated sealskin drag floats. The harpoons held firmly under the whale's skin and the float's retarding force tired a whale as it tried to escape. These inventions allowed the Eskimos to base their hunting economy on the sea's resources—seals, walrus, and whales—which were more reliable and less subject to disastrous fluctuations than those of the land. Using the drag float and improved harpoon head, Eskimos no longer needed to fight an animal directly by holding the harpoon line; instead the float did the work and took the punishment. So practical were these inventions that Yankee whalers adopted them in the nineteenth century, and Eskimos continue to use them today.

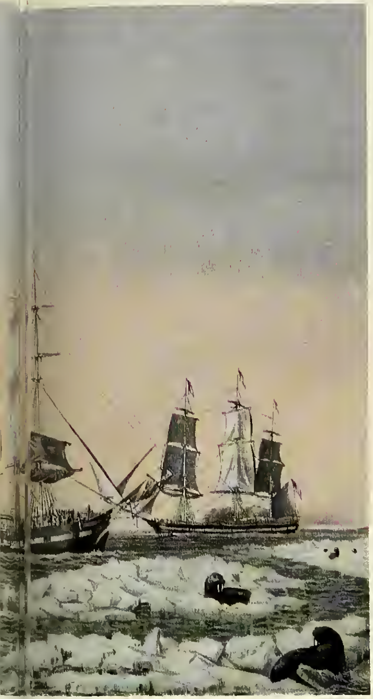
Another, equally important factor was an increasing Eskimo population that allowed each village to send out a number of crews. The catch increased dramatically when the Eskimos hunted in concert and concentrated on one whale at a time. When a whale was towing a dozen or more floats, tired and unable to submerge, it could easily be killed and towed to shore-fast ice for butchering.

Eskimos used all of the whale: skin, meat, and entrails for food; blubber for fuel; bones for tools and building materials; and baleen—the long, flexible plankton-straining plates in the whale's upper jaw—for lashings and craftwork. And they preserved the perishable parts year-round by storing them deep underground in cache pits dug into the permafrost.

In the early nineteenth century, Alaskan Eskimos probably took about forty whales a year, and this vast quantity of food allowed them to live, unlike other Eskimo groups, sedentarily in villages of up to 500 people, developing rich and complex social, artistic, and mythic traditions through which was shot the lore of the whale hunt, its glory and bounty.

But underscoring all was the Eskimos' fundamental understanding that without the whale, their society could not survive. Their palpable fragility was periodically driven home to them in lean years when adverse winds closed the shore leads all spring, forcing the whales far out to sea where the hunters could not reach them.

Despite these fluctuations the Eskimos and the whales lived together in a relatively stable ecosystem, but that stability was destroyed forever by the



*The painting* Right Whaling in the Bering Straits and Its Varieties *depicts different aspects of bowhead (also known as arctic right whales) whaling in the late nineteenth century. Fully loaded with oil, the ship under sail is heading past one of the Diomede Islands on its way to home port. The head of a bowhead is being hoisted aboard the ship in the center, while the ship at far right is boiling a batch of oil. The men in one of the dories are lancing a bowhead at the surface, under the watchful eyes of walruses hauled out on ice floes. Below: The portrait of Capt. Thomas Welcome Roys was taken in the mid-1860s. Note Roys's missing left hand, lost in an accident while experimenting with a rocket harpoon.*

arrival of commercial whaling fleets. Although they did not reach the Bering Strait until 120 years ago, the seeds of the destruction they caused had been sown a century earlier by stirrings within the New England whaling industry. In the 1750s ships first began to carry tryworks—for melting blubber into oil—allowing them to shed the fetters of their shore refining stations and range far into new waters.

They quickly entered the South Atlantic and by the 1790s had rounded Cape Horn. They reached Hawaii in 1819, then Japan, and in 1835 a Nantucket whaleship found whales off the northwest coast of America in the Gulf of Alaska. But by far the most important discovery came in 1848 when Capt. Thomas Roys of Sag Harbor, Long Island, decided to probe the waters of the Bering Strait. With a crew nearly mutinous from fear of the ice pack, Roys sailed his ship past the Aleutians into seas where only a handful of large vessels had ever been. His boldness was rewarded when he reached the Bering Strait and sailed into a field of whales—bowheads so numerous, fat, and docile that he filled

John Bockstoce

his ship with 1,800 barrels of oil after only a month's hunting. On his return to Hawaii word of his phenomenal success reached the Honolulu *Friend*, a missionary newspaper that whalemen carried round the world. So electrifying was the news that it set off an oil rush to the Bering Strait. Roys's discovery was fortunate for the world's whaling fleets because catches were declining in other seas. For a time the immensely productive whaling grounds of the western Arctic gave the whalers a reprieve. Before the industry's collapse in 1910, whaleships from the United States, Germany, France, Australia, and Hawaii made more than 2,600 cruises there, probably killing more than 20,000 bowheads.

But the waters of the Bering Strait were as dangerous as they were lucrative. In sixty years more than 150 ships were lost to gales, ice, and shoals. The industry was able to accept these terrible losses as long as the price of whale oil remained high and the catches large. But after the Civil War, both declined—oil because of the new petroleum industry and the catches because of the massive overhunting. Smart owners sold their ships; the others turned to walrus to increase their oil returns and in the 1870s nearly extirpated that population by killing as many as 100,000.

Although the whalers had relatively little direct contact with the Eskimos up to that time, their depletion of the whale and walrus stocks had an enormous impact on Eskimo society, and it was to grow greater still. In the late 1870s the price of baleen began to climb steeply, driven up by the fashion industry's call for narrow waists and the consequent need for baleen ("whalebone") as stiffeners in corsets. Because the bowheads produced the largest and finest quality of baleen, the whaling industry redoubled its efforts to catch them.

As the price of baleen rose in the 1880s (it would eventually pass five dollars a pound at dockside, making a fully grown bowhead worth $10,000 in turn-of-the-century dollars), the industry responded in two ways: it introduced steam auxiliary powered whaleships, which could pursue the whales into the farthest corners of the Arctic, and it set up shore-based whaling stations at many points in northwestern Alaska to hunt in the Eskimo fashion during the spring migration.

These last thrusts nearly drove the whales to extinction. Ironically, it was their very scarcity that saved them. As the number of whales declined, the price of baleen rose so high that it stimulated the introduction of cheap substitutes—chiefly spring steel—which quickly undercut the market, bringing it from five dollars a pound in 1907 to seven and a half cents in 1912. With the crash in prices came the industry's death. Soon the Eskimos were once again alone in hunting the bowhead. Although they had the seas to themselves for the first time in more than six decades, conditions were vastly different. There were few whales left to hunt, probably fewer than 3,000, and the Eskimos were now using manufactured whaling weapons—the darting gun and bomb-lance shoulder gun.

American whalemen had developed the guns to help prevent the loss of bowheads, which once harpooned, often escaped into the ice, towing lines, gear, and boats. The darting gun was mounted on the harpoon shaft and fired a small bomb into the whale the moment it was struck; the shoulder gun fired a similar bomb from a distance and aided in killing a wounded whale. Used together, they were effective tools for minimizing the number of "struck and lost" whales.

From about 1920 to the late 1960s the level of Eskimo whaling remained relatively constant with about fifty crews, based in villages from Saint Lawrence Island to Point Barrow, taking about ten to fifteen whales a year. The situation changed abruptly in the 1970s when the number of crews and whale catches began to increase dramatically, rising roughly threefold by 1976. Before this time the number of crews had been limited by the high cost of outfitting and maintaining them. But with the boom in Alaskan construction projects, particularly the trans-Alaska pipeline, it became possible for an ambitious Eskimo to earn the $9,000 or so necessary to buy the darting and shoulder guns, bombs, harpoons, floats, lines, boat, sleds, Skidoo, tent, stove, and food and thus to attain the prestigious position of whaling captain.

But the changing character of Eskimo whaling did not go unnoticed, and as the whale catch began to rise, so did scientists' and conservationists' concern about the impact on the bowheads. In particular, they worried about the unknown, but at least proportionate, increase in the number of

*On the ice a mile off Point Hope, Alaska, in the Chukchi Sea, Eskimo hunters watch and wait for bowheads passing on their spring migration from the Bering to the Beaufort seas. Up to a dozen native whaling crews from villages in the area participate in the annual hunt. With the use of such manufactured weapons as the darting gun and bomb-lance shoulder gun, the Eskimos have the potential for taking more bowheads than they ever have in the past.*

wounded whales—those struck and lost by darting or shoulder guns—that were not retrieved, many, if not most, of which are assumed to die.

As the catch rose in this decade (it reached 48 whales in 1976 with another 43 known to have been wounded; 28 and 77, respectively, in 1977), the Scientific Commitee of the IWC issued repeated warnings about the possible consequences of the increasing hunt. In 1976 it underscored its concern by passing a resolution asking the United States to reduce both the catch and the loss, but the United States took no important action regarding this request.

Then in 1977, with international sentiment rising against the uncontrolled bowhead hunt, the IWC voted to rescind the Eskimos' exemption from the otherwise total ban on bowhead whaling that had been in force since 1931. Ray Gambell wrote, "Clearly this was a drastic measure but the evidence presented by the scientists indicated that there was a real risk that the expanded slaughter of the bowhead whales, many of which were going to waste, would lead to the extinction of the stock within the foreseeable future."

Before 1977 the U.S. government apparently did little to keep the Eskimos abreast of developments in the IWC, so when word reached them in June 1977 of the IWC's decision, their reaction was sharp and angry. They claimed the action tampered with their domestic affairs and abrogated their inalienable native hunting rights.

Belatedly, in September 1977, the government began a series of public hearings to invite suggestions and criticism. One proposal called for distributing free beef to the Eskimos so that they would not have to shift their hunting pressure to the already depleted caribou herds. The Eskimos retorted that their nutritional needs are only half the problem; that equally important is their whole cultural matrix within which whaling plays a fundamental part; that removal of the whale hunt would result in starvation of another sort.

At the root of all the arguments was the central question of the number of bowheads alive today. Because very little is known about the whale's present or former numbers (it is the least known of all the great whales), the arguments for and against Eskimo whaling often return to one conjectural point or another. I know of no Eskimo who would question the importance of maintaining a viable bowhead population, yet few accept the U.S. government's most reliable current estimates of about 2,200 whales.

The IWC's action and the Eskimos' rebuttal put the government in an awkward position. During the summer and autumn of 1977 it became increasingly clear that the United States would have difficulty in resolving the contradiction between its previously strong stand in favor of whale conservation (the Marine Mammal Protection Act of 1972 is one expression of this) and the Carter administration's support for human and minority rights.

As a signatory to the conventions that established the IWC, the United photos by John Bockstoce

States is bound to carry out the IWC's recommendations within its boundaries, unless it files a formal objection to the action within ninety days of notification. To have accepted the 1977 recommendation would have meant halting Eskimo whaling: to have objected would, according to conservationists, have squandered the progress that had been made through the government's support of whale conservation.

The political atmosphere in Washington was highly charged in September and October 1977 as the antagonists waited for the government's response. Groups at high levels in the State Department (the government's representative on the IWC), the Department of Commerce (with responsibility for marine mammals), and the Department of the Interior (representing Alaska natives) debated the government's action.

On October 21 United States District Court Judge John J. Sirica, acting on a request from the newly formed Alaska Eskimo Whaling Commission, issued a temporary restraining order requiring the State Department to file a formal objection to the IWC's recommendation. But on the day before the ninety-day period expired, the State Department was able to have Sirica's order reversed by obtaining a ruling from the Circuit Court of Appeals in Washington. Finally, within hours of the deadline Chief Justice Warren E. Burger of the Supreme Court upheld the ruling of the Appeals Court by refusing to consider the document.

The government then sought the

*On the chase, a crew, far left, paddles after a bowhead they have spotted in the vicinity. After the whale has been harpooned and killed, cooperating crews gather around the floating carcass, left. The whale's flippers are tied together, below, to facilitate towing the dead animal to a spot where the butchering will take place. The skin, meat, and entrails will be used for food, the blubber for oil, the bones for tools, and the baleen for lashings and craftwork.*

only middle ground available, proposing a bowhead quota of fifteen whales caught or thirty struck, whichever came first, as well as the development of a strong research program to learn more about the whales' biology and numbers. In December the IWC rejected the proposed quotas and agreed to a limit of twelve caught or eighteen struck.

The Alaska Eskimo Whaling Commission observers at the meeting quickly protested the quotas, claiming they were insufficient to meet the nutritional needs of the whaling villages. At least one observer predicted that the quota would be violated, but most agreed to abide by it to demonstrate their good faith, their ability to regulate themselves, and their strong desire to participate in the formation of new regulations.

They were largely successful. Although the village of Barrow exceeded its quota by one whale, the Eskimos stayed within the overall limits. At the June 1978 IWC meeting the United States presented its estimate of the bowhead population, 2,260 whales, with the caveat that the counting program is in its infancy and that more surveys must be conducted before full reliance can be placed on the figures. And the IWC, expressing sympathy for the problems of the Eskimos, increased the quota to eighteen whales caught or twenty-seven struck for the 1979 season.

Nevertheless, in July 1978 the Eskimos of the North Slope Borough (comprising the whaling villages north of Kivalina) brought suit against the government, claiming that the regulations

John Bockstoce

Chlaus Lötscher

were illegal because the IWC convention was not established to include aboriginal whaling. In early 1979 the court dismissed the action, stating that the convention was a matter of foreign policy, hence outside its purview. The Eskimos appealed the ruling in the Ninth Circuit Court of Appeals, where the case remains as this is being written.

Then in February 1979 the IWC and the Department of Commerce, wanting to understand the issues more fully and to seek equitable solutions, jointly convened an international group of scientists to study the questions. The scientists (specialists in arctic biology, anthropology, and nutrition) concluded that although there was no credible scientific basis for allowing *any* bowhead catch, and although alternative sources of food are available, whaling is so culturally important to the Eskimos that it should be allowed to continue at some level.

Although the Eskimos, the IWC, and the U.S. government temporarily achieved an uneasy *modus vivendi*, it did not last long. During the spring of 1979 there was a growing wave of sentiment among the Eskimos—by no means uniform, but centered particularly in Barrow—to ignore the IWC quota and to accept the Alaska Eskimo Whaling Commission's contention that forty-eight whales are a safe and desirable number to harvest. (The Eskimos apparently reached this figure through a tactical blunder by Richard Frank, U.S. commissioner to the IWC, who stated that a harvest of 2 percent of the total bowhead population was a reasonable figure—an assertion strongly denied by many scientists.) But the 1979 season turned out to be poor, and the Eskimos were unable to reach even the IWC quota, thus deferring the issue until 1980.

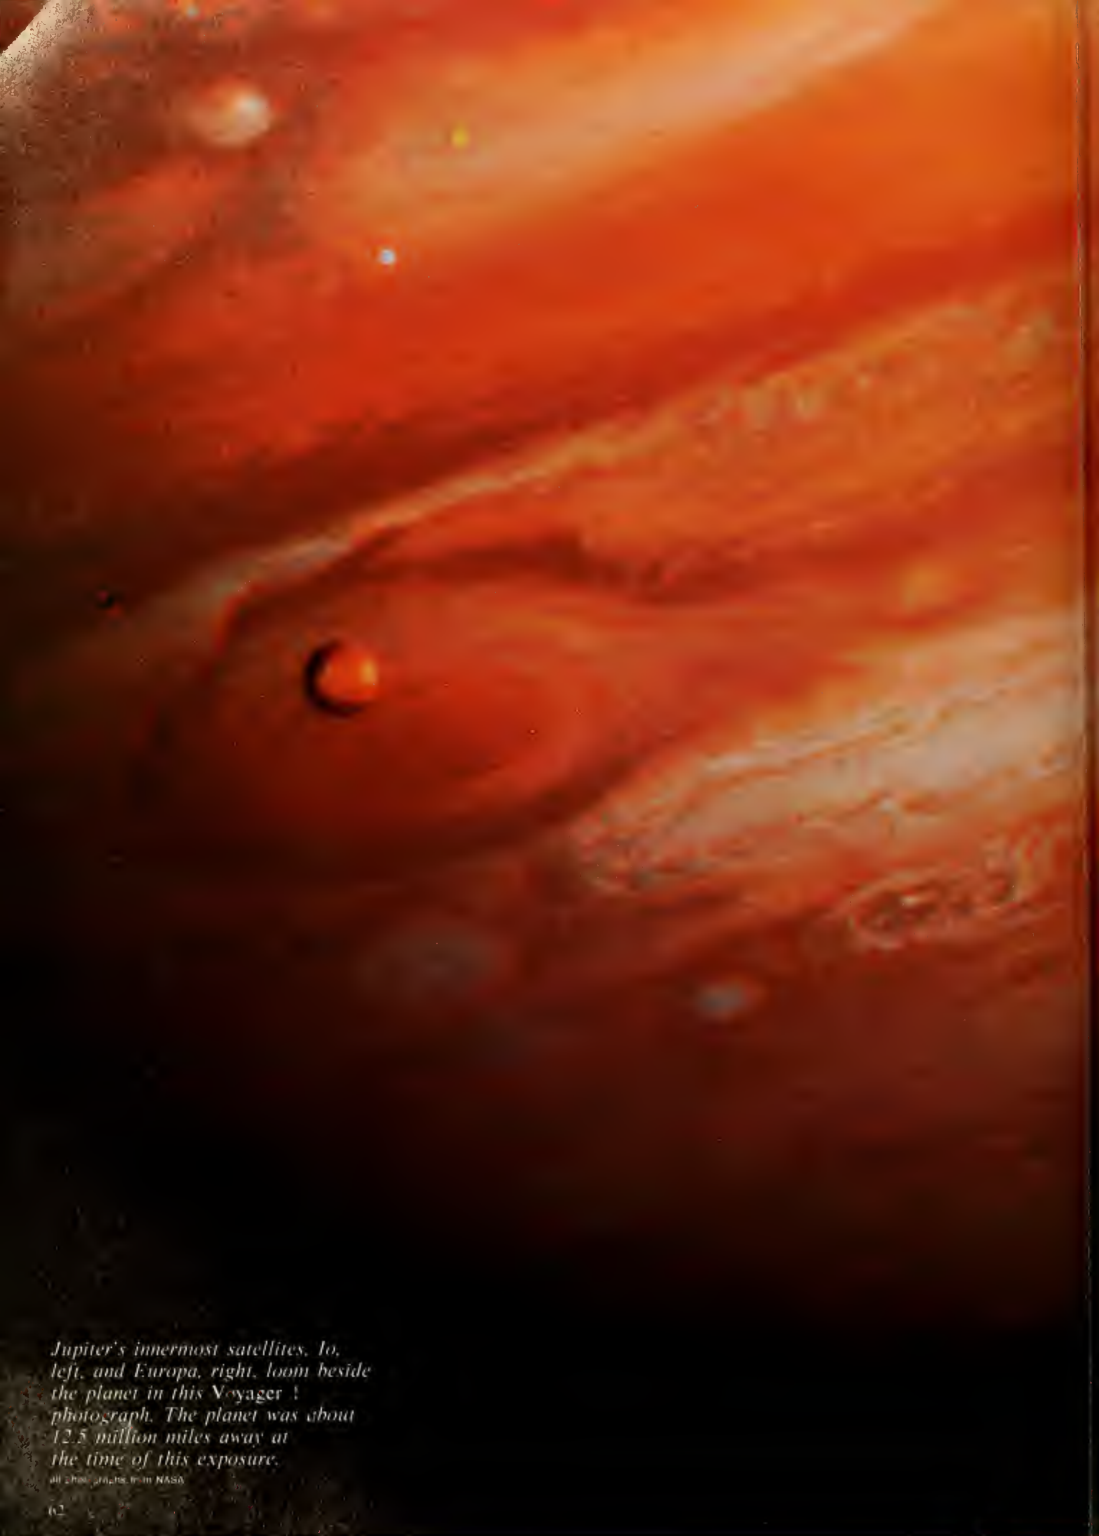
If the Eskimos exceed the IWC quota in 1980, the government will be in an extremely difficult position—and one it is possibly unprepared to deal with. Hitherto, the government seems to have been preoccupied with the relatively noncontroversial questions of counting the whales and of sponsoring other basic research, but equally, it seems to have ignored the serious social dilemma of the bowhead issue by assuming that, if need be, law enforcement can ultimately control the problem.

Conventional law enforcement is, of course, based on a general public acceptance of laws and a disapproval of lawbreaking. In the bowhead problem, however, the government confronts a society that has, on this issue, lost most of whatever confidence it once had in the government; to many Eskimos the issue is increasingly seen as racial. Some law enforcement officials concede that it would be exceedingly difficult to enforce any laws regarding whaling in northern Alaska.

What will happen this month and what the government's response will be remain to be seen. But one thing is certain: the bowhead whale issue is far from settled and beyond it lies the broader question—as yet unanswered—of the rights of Native Americans versus those of all Americans regarding the maintenance of wildlife and ways of life, together, in a shrinking world. ☐

Chlaus Lötscher

*Using pulleys, whalers from the Point Hope area haul the carcass of a bowhead onto the shore ice, far left. The butchering begins with the skin being sliced in a pattern of even strips, left and below; in this case by hunters from Gambell. As important as the meat and other products derived from bowheads is the actual hunt. The activities that accompany whale hunting are deeply woven into the matrix of Eskimo culture, reaffirming cultural unity and kinship and other social ties.*



*Jupiter's innermost satellites, Io, left, and Europa, right, loom beside the planet in this Voyager 1 photograph. The planet was about 12.5 million miles away at the time of this exposure.*

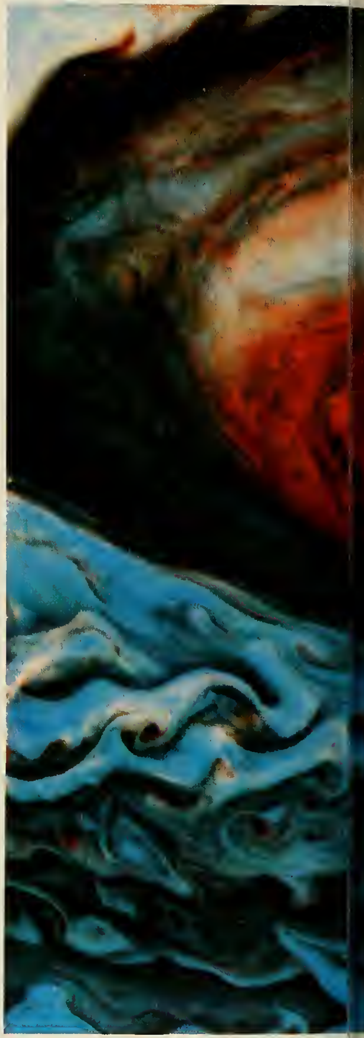
# By Jove

*Photographs and data from the* Voyager *spacecraft that flew past Jupiter yielded several surprises about the planet and its satellites*

### by Andrew P. Ingersoll

The two *Voyager* spacecraft that flew by Jupiter in March and July of 1979 discovered several unanticipated things: a many-particle ring close to Jupiter, a new satellite at the edge of the ring, active sulfur volcanoes on the satellite Io, lightning and auroras on Jupiter (the latter generated by particles from Io's orbit), and turbulence that acts to increase rather than decrease the energy of Jupiter's large-scale cloud motions. Besides their intrinsic interest, these discoveries help us understand related phenomena on the sun, the earth and other planets, and provide clues about how the solar system began and how it is evolving.

Sending a spacecraft to Jupiter is



*The Great Red Spot, an atmospheric storm about twice the size of the earth, and the turbulent clouds around it are shown in exaggerated color. The bluish oval at the bottom is a smaller storm system.*

like sending one to another solar system, something astronomers would like to do but haven't done yet. Jupiter, the giant planet, resembles the sun in many ways. Both release heat internally, although by different mechanisms. Both are fluid rather than solid objects, with complicated patterns of surface flow features. The same elements—mainly hydrogen, helium, carbon, oxygen, nitrogen, and sulfur—are present on both objects in nearly the same proportions. Jupiter has fourteen known satellites; the sun has nine major satellites (the planets) and many minor ones (comets and asteroids). And both Jupiter and the sun have left records in the surfaces and bulk properties of their satellites that tell of violent early histories.

It was known before *Voyager* that Jupiter is mostly hydrogen. No other substance has such a low density for an object of such large size. Jupiter's density is only slightly greater than that of water and is about one-quarter that of the earth. The next most abundant Jovian element, helium, contributes about 20 percent of the planet's mass; all other elements together contribute an additional 5 percent.

Jupiter's internal heat had been detected from high-altitude aircraft before *Voyager*. More refined measurements by *Pioneer* and *Voyager* spacecraft confirmed calculations based on the assumption that this energy was trapped when Jupiter formed. This confirmation lends support to the idea that both Jupiter and the sun started as dispersed clouds of dust and gas 4.6 billion years ago. High temperatures were generated as the material fell inward. On the sun, nuclear fusion released additional energy as hydrogen atoms began sticking together to form helium. On Jupiter, internal temperatures were never high enough for nuclear fusion to occur, but enough heat was generated to last into the present era. The fact that Jupiter now radiates between 1.5 and 2.0 times the energy it receives from the sun agrees well with theory.

Another current idea about solar system formation is that high temperatures on the early sun determined the composition of the planets. An object forming from a collapsing gas-dust cloud is thought to pass through a violent early phase. During this phase, gas and volatile ices are driven from the region near the central body—the sun. Satellites (planets) forming from material in this region are made of metals and their oxides. Satellites forming farther away are made of the more abundant gases and ices. This accounts qualitatively for the differences between the rocky inner terrestrial planets and the gaseous outer planets of the solar system. It also accounts for density differences between Jupiter's four large satellites—Io, Europa, Ganymede, and Callisto—also known after their discoverer as the Galilean satellites.

The density of a satellite-sized object is largely a function of its composition. Metals are the most dense, followed by metallic oxides (rocks), then ices and liquids, and finally, gases. *Voyager* determined the mass of each Galilean satellite by measuring its gravitational pull. The volume was determined from *Voyager* images. These observations confirmed earlier inferences that the innermost Galilean satellites, Io and Europa, are mostly rock, while the outer satellites, Ganymede and Callisto, have increasing proportions of ices and liquids. Because hydrogen and oxygen are abundant elements, water is likely to be the plentiful ice on the outer Galilean satellites.

Thus *Voyager* lent support to the idea that the sun and planets formed simultaneously from a cloud of dust and gas. Star formation by this process seems relatively common throughout the universe. Therefore, by inference, planetary formation is also relatively common.

Planetary rings provide further clues to the origin and evolution of planets and satellites, so *Voyager*'s discovery of Jupiter's ring is potentially significant. Material that is orbiting a planet can pull itself together to form a satellite unless the competing pulls of the planet's gravity and centrifugal force due to orbital motion are too strong. Rings form from material that is inside the so-called Roche limit, where the two competing effects balance each other. Saturn's ring consists largely of snowball-sized chunks of water ice, gently rubbing together as the inner material slowly overtakes the outer material in its orbital motion. Collisions long ago damped out any large out-of-plane motion. Since snowball-sized particles have stable, long-lived orbits, Saturn's ring, at least, could be as old as the planet itself.

Jupiter's ring by comparison is exceedingly thin—it was only discovered when the *Voyager* spacecraft's imaging system took a picture showing the ring edge-on. In this configuration the light rays traverse the maximum possible path through the rings, and the contrast between the ring and space is greatest. Although snowball-sized particles cannot be ruled out, most of the

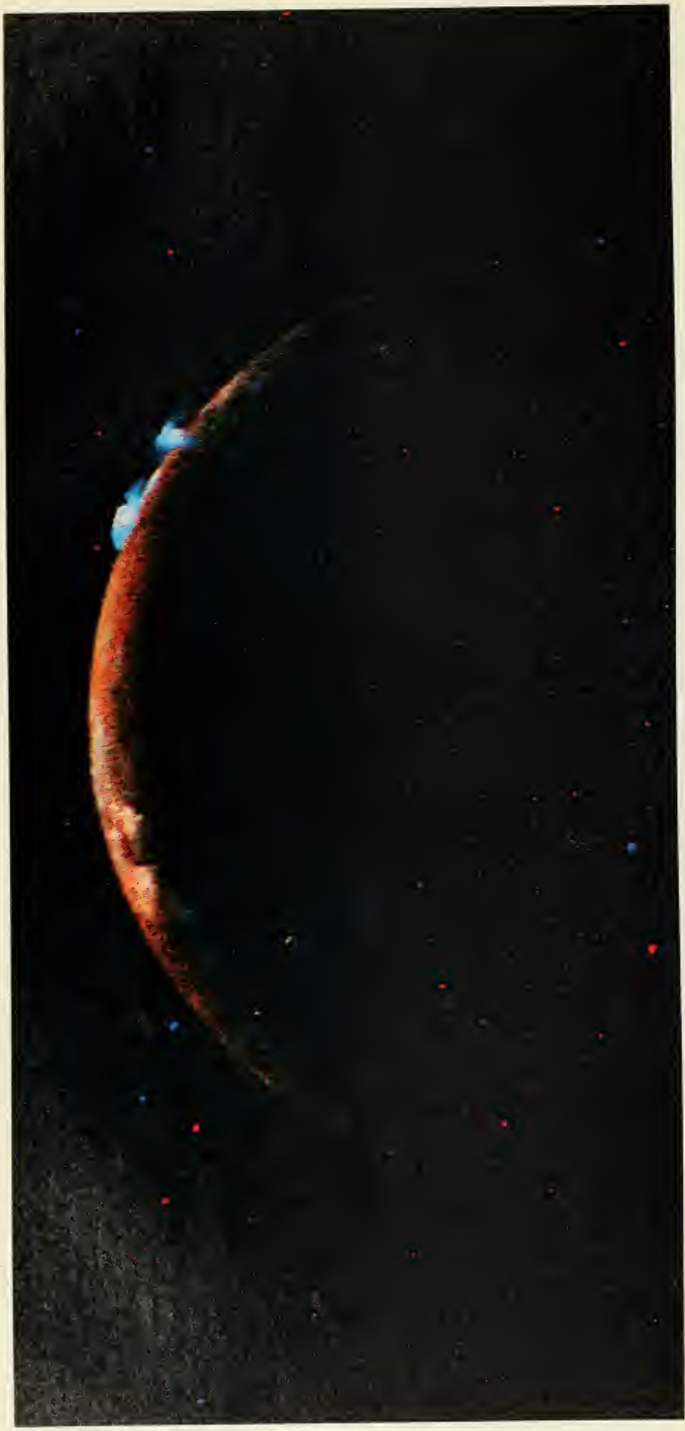
particles appear to be small, about one ten-thousandth of an inch in size.

These inferences are based on the way the rings scatter sunlight. Particles of this size are subject to light pressure and other small forces that cause their orbits to decay. Eventually the particles spiral in to the planet's atmosphere and are lost. These particles cannot be as old as Jupiter itself.

*Voyager* also discovered a small satellite orbiting right at the outer edge of the ring. The satellite undoubtedly helps to sharpen this edge and fix its location. The satellite might also be the source of material for the ring, which could therefore be a secondary object, owing its existence to the small satellite discovered by *Voyager.*

During the final stage of planetary formation, as the last large objects were swept up by the planets and satellites, planet surfaces were bombarded by these large objects at high velocity. Many planets and satellites still bear the scars of this last phase of planetary accretion. The moon, Mars, and Mercury all have terrain that is entirely covered by craters. Evidence that these surfaces are ancient comes from the current rate of formation of craters, which is far lower than that required to cover these surfaces in the time since the solar system began 4.6 billion years ago. Obviously, the cratering rate was higher when the planets were still accreting material. It is now believed that this heavy cratering phase lasted for less than 10 percent of the current age of the solar system. Regions that are not saturated with craters were presumably "resurfaced" after that period ended.

*Voyager* images of the four large Jovian satellites clearly show an increase of surface ages as one proceeds outward. That is, the number of craters per unit area increases with distance from Jupiter. Since all the satellites are thought to have formed at the same time, with the same heavy flux of



impacting bodies, the differences in surface ages must reflect the different rates of burial of features.

By the above reasoning, the outermost large satellite, Callisto, is an inactive body whose surface hasn't changed for 4 billion years. The next satellite, Ganymede, shows a mixture of surfaces, some heavily cratered, and some bearing evidence of more recent faulting and other internal activity. The third satellite inward, Europa, is crisscrossed with linear bands of internal origin, but has only a small number of craters (three were seen by the *Voyager* cameras). Interestingly, the earth has about the same density of impact craters in this size range, approximately ten miles in diameter. The low density on earth probably reflects the effects of erosion and sedimentation in obliterating ancient features.

Jupiter's innermost large satellite, Io, has no visible craters. Assuming a flux of impacting bodies today that is similar to that on the earth, the rate of burial would have to be at least one inch in twenty-five years in order to bury the craters that would otherwise be visible. This would be a high rate of burial for an object such as our moon, which has no atmosphere or active volcanoes. The difference between Io and our moon is undoubtedly related to the active volcanoes and other geologic activity discovered by *Voyager* on Io.

Current understanding of this high activity has come partly from theory and partly from new knowledge of the environment around Io. Both the gravitational and magnetic fields of Jupiter are important. A small object in orbit around Jupiter would be in a weightless state and therefore would experience no internal stresses due to Jupiter's gravity. However, a satellite-sized object experiences different amounts of gravity at different locations about its surface and interior. This differential pull accounts for the tides, and tides are very powerful on an object like Io. It was recently pointed out that the other Jovian satellites cause Io to bob up and down in Jupi-

*Volcanic eruptions on Io, some with plumes almost 200 miles high, were first found by Voyager 1. This evidence of volcanic and other geologic activity on the satellite was unexpected.*

ter's gravity and therefore to experience large changes in the tidal forces. Io's tidal flexing creates heat, which presumably has melted the satellite's interior. The heat escapes when molten material and hot volcanic gases reach the surface. Eruptions of eight active volcanoes were observed on Io by *Voyager*.

In addition, Io is subjected to steady bombardment of ions and electrons that are trapped in Jupiter's powerful magnetic field. This magnetic field is tied to Jupiter, and rotates with a ten-hour period. At Io's orbit, the speed of rotation is huge, thirty-five miles per second. This causes large electric currents to flow in the vicinity of Io, either through the satellite itself, through its tenuous atmosphere, or through the doughnut-shaped torus that constitutes its orbit around Jupiter. These electric currents can also cause heating, which may acount for some of the obliteration of surface features. In contrast, the earth's moon orbits well outside the influence of the earth's magnetic field and so is spared the electrical phenomena that Io experiences.

The activity at Io causes other problems for that moon-sized object. Whereas Jupiter's outer satellites have retained large amounts of water, Io has literally been "cooked" to a point at which only relatively less volatile substances remain to power the volcanoes. One such substance is sulfur. The rich colors of Io are probably due to sulfur molecules. *Voyager* identified sulfur dioxide frost in the spectrum of light reflected from the surface. Presumably this frozen crust gradually thickens as more material is ejected from the volcanoes, and eventually melts under its own weight to form a sulfur dioxide ocean. Io's internal heat, generated by tides or electrical currents, then vaporizes the sulfur dioxide, which breaks through the icy crust and erupts again as volcanic gas. The expansion of the gas is strong enough to send plumes almost 200 miles high into the partial vacuum around Io, but not strong enough to cause a major part of the gas to escape Io's gravity. A substance such as water, which is more easily destroyed in space, would presumably have escaped long ago under these conditions.

Still, some of the sulfur does escape. Light from electrically charged sulfur was detected by *Voyager* coming from the torus defined by Io's orbit. This tenuous ring of charged particles, with Jupiter at its center, seems to be the source of huge auroras that cause Jupiter's atmosphere to "glow" in ultraviolet light. The sulfur ions and their electrons are driven by electrical forces down the magnetic field lines from Io's torus into ring-shaped zones at Jupiter's north and south poles. The role of the sulfur torus was not anticipated before *Voyager*. On the earth, auroras are also due to the impact of charged particles from outside the atmosphere, but those particles originate on the sun rather than on the earth's moon.

The other Galilean satellites may also have oceans beneath their icy crusts. As mentioned earlier, their bulk densities suggest that the proportion of lighter substances such as water is greater for the satellites farther from Jupiter. Io's bulk density is basically the same as rock, and rocky mountain ranges protrude from the flat, frozen crust of the sulfur or sulfur dioxide ocean. In contrast, the outer satellites have extremely subdued topographic relief. The craters on Callisto and Ganymede do not have high, raised rims and deep central depressions like those on the moon and Mercury. The outer satellite craters are made visible by variations in color and texture of the material that was posed by the impacting events. This lack of topographic relief indicates a weak crust at the time craters were forming and is consistent with the hypothesis of a high ice-to-rock ratio for these satellites.

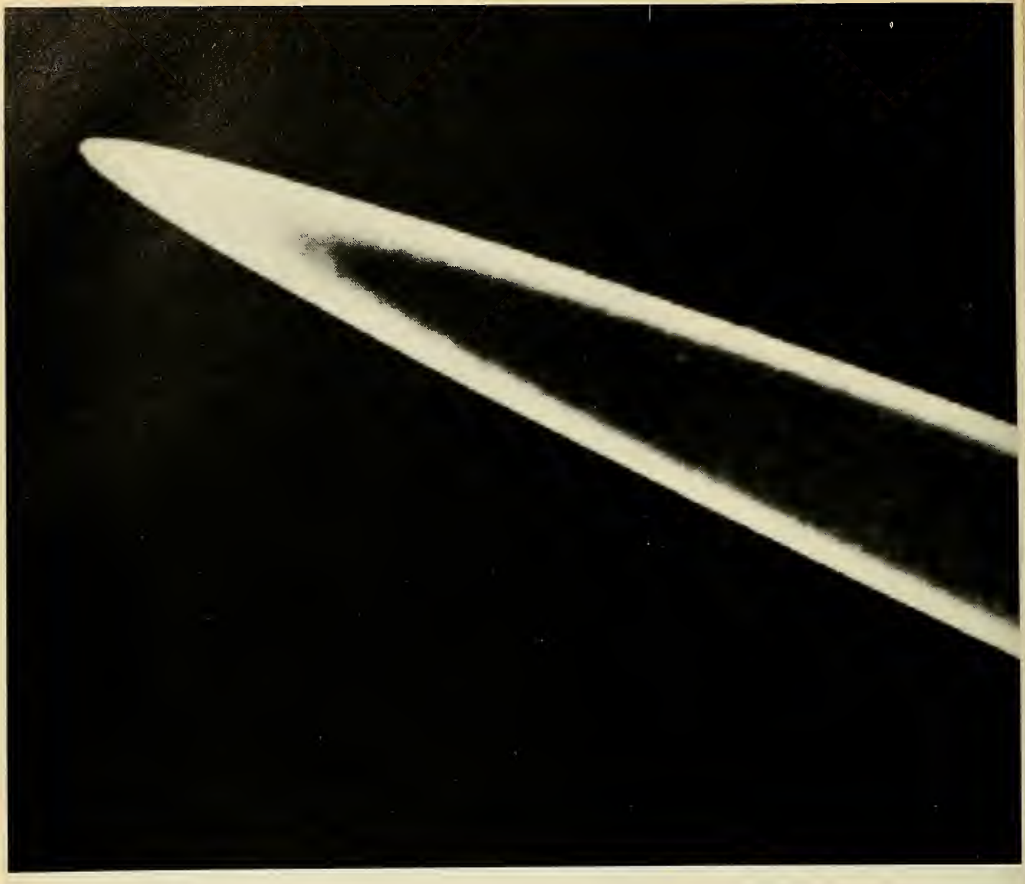
Jupiter itself exhibits a rich variety of surface markings, all having to do with the dynamics of the atmosphere. Every visible feature is a cloud. The solid surface, if there is one, is just a rocky core about one-eighth the size of the planet. Only the minor atmospheric constituents can condense to form solid or liquid cloud particles that are visible in a photograph. And only a small fraction of the condensates are colored. The most abundant condensing substances—water, ammonia, and ammonium hydrosulfide—form white crystals when they condense. Thus color is a subtle process on Jupiter, involving minute amounts of trace constituents. Yet color is one of the spectacular features of the *Voyager* images.

Again, as on Io, sulfur is a prime candidate as the coloring agent. Images of Io and Jupiter together show many of the same colors. However, in a hydrogen-rich atmosphere, most of the sulfur is tied up as hydrogen sulfide gas. This chemical equilibrium is constantly being disturbed by several processes that have sufficient energy to break the bond of sulfur and hydrogen. One of these processes is lightning, which was discovered by *Voyager* in photographs of Jupiter's night side and in the electromagnetic emissions that propagate out of the atmosphere. Another is ultraviolet radiation from the sun striking the top of the atmosphere. A third is the charged particle flux from Io and Jupiter's magnetosphere. And a fourth process that can alter the chemical composition is rapid transport of material from great depths and high temperatures in Jupiter's interior. Besides sulfur, other colored substances that are produced in these ways are phosphorus and organic (carbon) compounds.

There is strong evidence that Jupiter's different colors are associated with clouds at different altitudes. In some regions the dominant vertical motion is upward, causing white and red clouds to form, while in other regions the dominant motion is downward, causing brown and blue colors.

The above processes make colors, but do not account for the large-scale patterns of color or the long lifetimes of the patterns. For instance, the Great Red Spot has been in existence for more than 100 years, and may be the same feature reported by astronomers using the first telescopes 300 years ago. The three white ovals in a latitude band to the south of the Red Spot formed about forty years ago and have changed little since that time. And the large bands that circle the planet at constant latitude are also very stable. These bands—dark belts and lighter zones—change their appearance in time periods of months to years, but on the average their positions and widths are stable.

This long-term stability is remarkable for atmospheric features that are not directly tied to a solid surface. Observations by *Voyager* of vigorous turbulence on small scales only heightens the mystery. For example, small spots circle the Red Spot with periods of six to ten days. Features in the disturbed region to the west of the Red Spot last only one or two days. At all latitudes the dominant pattern of motion involves counterflowing eastward and westward currents alternating in latitude. Small spots caught between two such currents roll like ball bearings with periods of several days. It is remarkable that any features can last



*This thin ring around Jupiter was discovered by* Voyager 1. *It contains tiny particles of about one ten-thousandth of an inch in radius.*

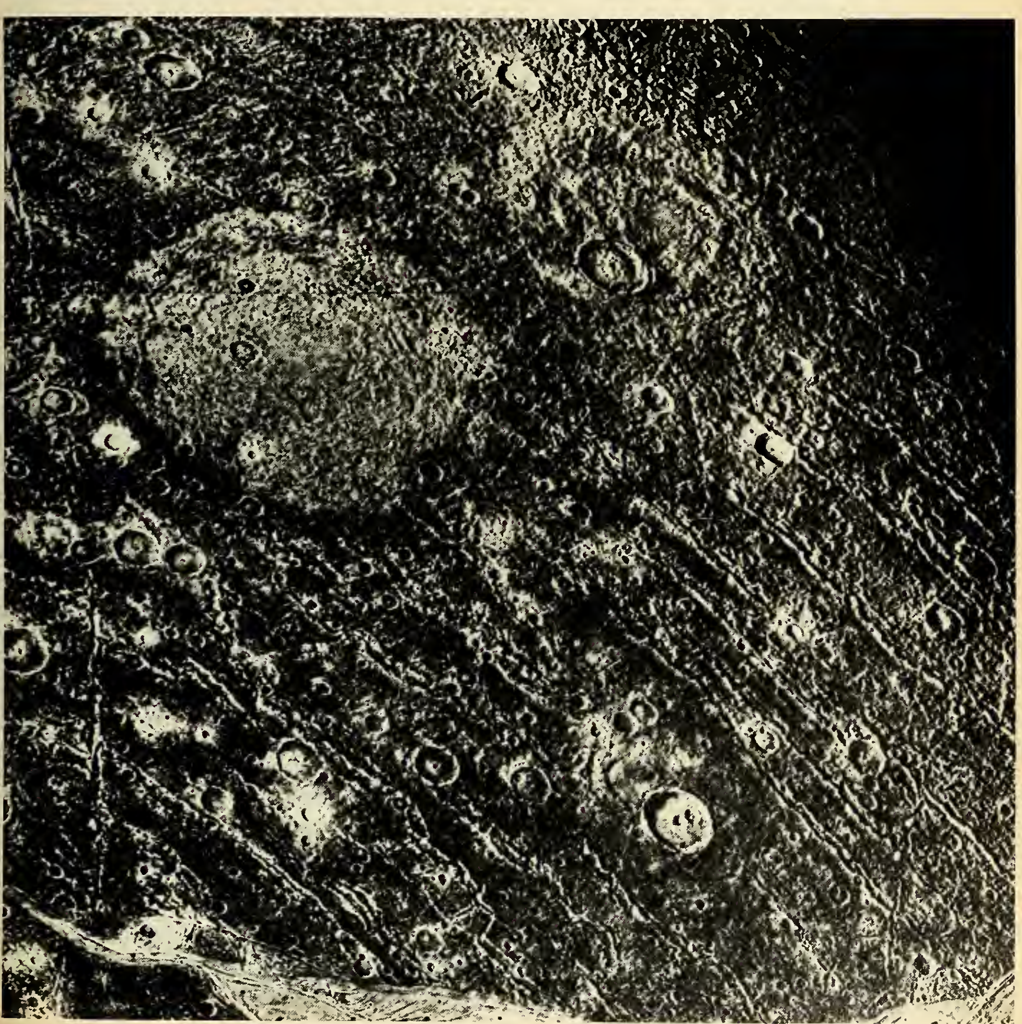
longer than the turbulence itself, that is, longer than several days.

The motions described above are all measured relative to Jupiter's rapidly rotating interior. The winds reach speeds greater than 300 miles per hour. As on the earth, the rotation of the planet as a whole plays an important role in the dynamics of these features. Spots whose rotation is clockwise in the Northern Hemisphere or counterclockwise in the Southern Hemisphere are high-pressure regions—at least at the cloud tops where motions are observed. Spots whose rotation is opposite are low-pressure regions. These highs and lows at the cloud tops may be caused by expansion or contraction of the gas underneath. In this respect, the large high-pressure systems on Jupiter resemble such low-pressure systems on the earth as extratropical cyclones and hurricanes. Both systems are formed by the vertical motion of warm air at their centers. The presence of a solid surface underneath accounts for the differences in the circulations at high altitudes. On the earth, rising air is not immediately replaced at the surface, and a low pressure area forms. On Jupiter, rising air is immediately replaced from below; the incoming air lifts the column and causes high pressures at high altitudes.

The above qualitative associations are confirmed by temperature measurements made by instruments on the *Voyager* spacecraft. The explanations do not, however, account for the long lifetimes or banded appearance of Jovian atmospheric features. This problem has not been solved, but the answer may lie in the absence of a solid underlying surface and in the presence of an internal heat source.

Careful study of the eddy motions divulged in sequences of *Voyager* images has revealed that the short-lived Jovian eddies do not destroy the large-scale structures. It was discovered that the eddies transfer their kinetic energy into, not out of, the counterflowing east–west currents. Presumably this energy is dissipated to heat when the currents rub against the layers underneath. The energy for the eddies must come from another source, in this case the buoyancy of hot and cold parcels of gas. Such a transfer of energy also seems to maintain the earth's mid-latitude jet streams and some of the major ocean currents such as the Gulf Stream in the Atlantic and Kuroshio in the Pacific. However, terrestrial ocean currents owe their permanent configurations to continental boundaries, and the earth's atmospheric jet streams meander over wide ranges of latitude. Thus it is surprising that Jupiter should have as many cloud bands as are observed and that they should occupy such permanent locations.

Evidence that the Jovian currents may extend deep into the atmosphere beneath the clouds comes from the fact that the cloud colors and visible markings change more than the currents do. Observations of the motions of large spots go back over seventy years. Owing to lack of suitable features for tracking, not all Jovian currents are visible from the earth at any one time. Nevertheless, virtually every major current that has ever been seen in seventy years of earth-based observations is visible in any ten-hour sequence of high-resolution *Voyager* images. The cloud bands, however, change their appearance and color on a time scale of a few years. For instance, dramatic changes occurred in the clouds during the four to five years between the *Pioneer* spacecraft encounters and the *Voyager* encounters, yet the latitudes of the currents did not change. Thus the differences between Jupiter and the earth with respect to longevity of flow patterns may be due to the great mass and huge inertia of the deep atmospheric motions below the Jovian clouds. The role of the deep atmosphere remains one of the major unknowns in the study of Jupiter's atmospheric circulations. ☐



*Ganymede, the third of the Galilean satellites, as seen from a distance of about 53 thousand miles, exhibits a variety of impact craters of different ages. The brightest craters are the youngest.*

# Jefferson Davis's Camel Corps

*The feasibility of a camel cavalry was tested in the southwestern United States*

**by Gerald Carson**

In the late 1840s a group of junior army officers engaged in protecting the southwestern frontier of the United States—a mountainous terrain deficient in the grass and water needed by cavalry horses and pack mules and recently doubled in length by the annexation of Texas—began to think about camels.

One officer, Maj. Henry Constantine Wayne, was especially enthusiastic about the concept. Wayne was a West Pointer who had been brevetted for gallantry at Contreras and Churubusco in the Mexican War. He proceeded to dig deeply into the subject of camels—the different breeds, their characteristics, economic usefulness, and thriftiness in Asia and Africa. He found that there were two distinct species: the one-humped, or Arabian, camel, *Camelus dromedarius*, poetically called the ship of the desert and used chiefly as a saddle animal; and the two-humped, or Bactrian, *Camelus bactrianus*, a heavier, slower-moving beast of burden. The dromedary was simply an Arabian camel of higher breeding, great speed, and endurance, but not a different animal, zoologically speaking.

Studying isothermal lines Major Wayne became convinced that climatic conditions in Texas, New Mexico, and California corresponded to the mean temperatures within the parallels of latitude limiting what he called Camel Land. It was beyond argument that in their native environment camels moved faster, endured longer, carried more freight, and required less water and forage than horses, mules, or oxen.

Working his way up through the military bureaucracy, Wayne made a formal recommendation to the War Department that the importation of camels should be undertaken to test the feasibility of camel cavalry. The idea reached Sen. Jefferson Davis, then chairman of the Senate Committee on Military Affairs. He liked it. And he knew, as a matter of history, that the French had used the dromedary with marked success in Egypt during the Napoleonic campaign and again in Algeria. Davis had commanded a regiment during the Mexican War and understood the problems of military and civilian communication in arid regions. He also wanted surveying and reconnaissance work done on an all-weather, transcontinental railroad route south of the Gila River (later the line of the Southern Pacific Railroad) that would close the vast gap between the civilization and commerce of the eastern states and the defenseless Pacific coast, and permit the South to share the economic advantages of the China trade and the development of the gold fields of California. The problem was acute, calling for imaginative new initiatives to make secure the onward march of empire.

In 1851 Senator Davis tried to get an amendment to the army appropriation bill for the purchase of fifty camels and the hire of ten camel drivers, but objections were raised that the west was too cold for the animals, the expense too extravagant—the sum requested was $30,000—and a good deal of humor was expended upon the project in the Senate. A year later the House of Representatives, with support from the War Department, passed a camel bill but the Senate again rejected it.

Public support appeared in favor of the proposal. John Russell Bartlett, author and ethnologist, who had spent three years in the southwest as U. S. commissioner to run the boundary line between the United States and Mexico under the Treaty of Guadalupe Hi-

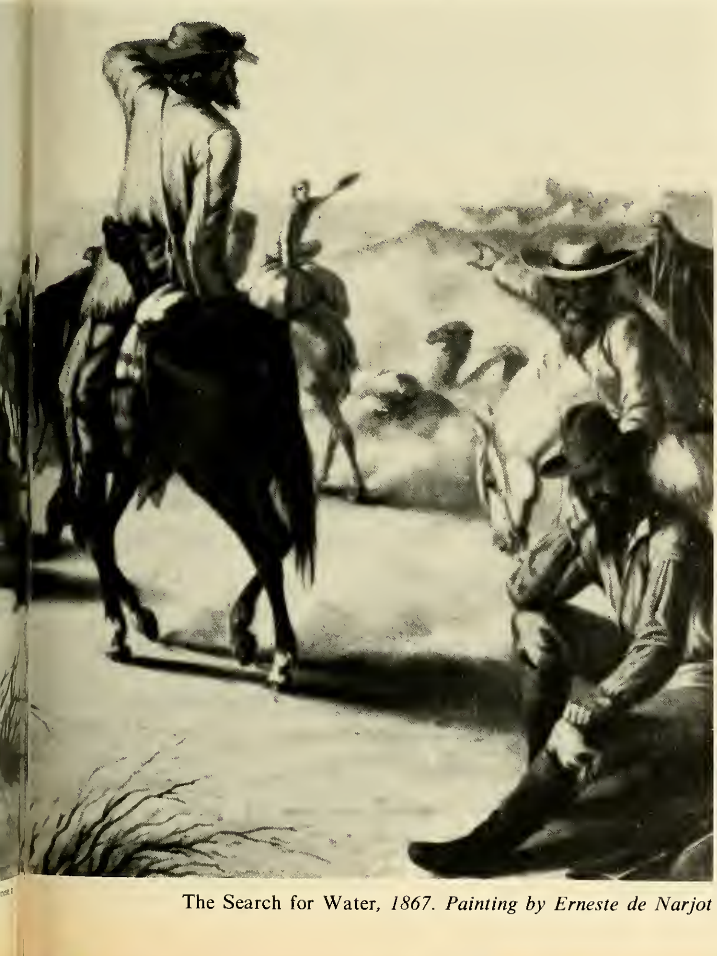
dalgo; archeologist George Robins Gliddon, who had lived in Egypt for twenty-three years and served there as vice-consul; and George Perkins Marsh, traveler, diplomat, and physiographer, who had lived in the Levant, all spoke up for the camel experiment. Marsh lectured on the subject at the Smithsonian Institution and wrote a book about it entitled *The Camel: His Organization, Habits, and Uses, Considered with Reference to His Introduction into the United States.*



The Search for Water, *1867. Painting by Erneste de Narjot*

A year later (1853) Jefferson Davis became Secretary of War in the administration of Pres. Franklin Pierce and strongly recommended the camel experiment to Congress but without success. In 1854, his annual report to the president again stressed the tenuous line of communication through Texas to the department of the Pacific and the large population of Indians in the region who were nomadic and predatory. "I again invite attention," Davis wrote,

> to the advantages to be anticipated from the use of camels and dromedaries for military and other purposes, and, for the reasons set forth in my last annual report, recommend that an appropriation be made to introduce a small number of the several varieties of this animal, to test their adaptation to our country.

In 1855, with support from western legislators and President Pierce, Davis at last secured the sum of $30,000 for camel purchases. The secretary moved quickly to procure the animals. The mission was placed in the hands of Major Wayne and Lt. David D. Porter of the Navy, who later achieved national fame for distinguished service during the Civil War.

As directed, in precise and meticulous orders from Secretary Davis, Wayne visited zoological gardens in England and France. In Paris, he also consulted with French officers who had had experience with camels in Algeria. Lieutenant Porter, in command of the storeship *Supply*, sailed to Italy; at Pisa he inspected camels owned by the duke of Tuscany, and reported that each camel could do the work of four horses. Wayne and Porter rendezvoused at Spezzia, then visited various ports in the eastern Mediterranean—Tunis, Smyrna, Salonika, and Constantinople. In a gesture of goodwill to the president and people of the United States, Mohammed Pasha, the bey of Tunis, gave the two officers a camel but it had to be unloaded at Alexandria because it developed an ailment called the itch, for which there was no cure. By this time Wayne and Porter had become expert camel traders and although many tried to defraud them, they could not be imposed upon. Past mistakes were liquidated; in one instance they sold a couple of unsuitable animals to a butcher at Constantinople, "who bought them," Porter said, "for purposes known only to himself."

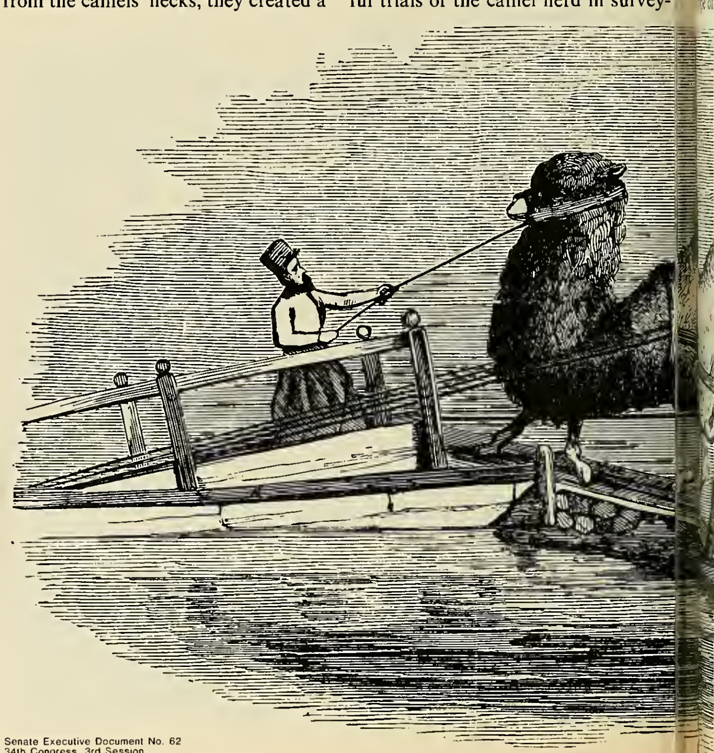
After a visit to Egypt the *Supply* sailed back to Smyrna to complete the cargo and on February 15, 1856, headed for the Texas gulf coast with nine swift dromedaries from Egypt, twenty burden camels, and four others of mixed breed. On the three-month return trip, the weather was often so rough that the beasts had to be strapped down on the camel deck to save them from injury. Wayne occupied himself in writing a long report to Secretary Davis and translating various works about camels from the French, while Porter kept a daily journal about the animals' health and their management aboard ship, recording in detail how they were rubbed, curried, oiled, and salted, also noting the birth of a baby camel at sea, which was named "Uncle Sam."

The ship dropped anchor in the Bay of Matagorda eight miles from Indianola, Texas, on the afternoon of April 29, 1856. The camels were in the care of native drivers, grouped together by the Americans under the generic name "Arabs," regardless of their ethnic mix. They had acquired anglicized names and nicknames, such as Greek George, Long Tom, Mico, and Hi-Jolly, which was Texan for Hadji Ali. Wearing red blankets, the animals were lightered to the wharf at Powder Point, three miles below Indianola. The camels, touching solid earth after their long confinement, reared, kicked, cried out, and broke halters, while the inhabitants of Indianola and Powder Point happily concluded that a free circus had come to town. Porter speculated that camel fighting might recommend his ungainly charges to the indigenous sporting population.

The *Supply* promptly undertook a second voyage, and early in 1857, forty-four camels were landed at the mouth of the Mississippi River. A third load was delivered at Indianola by private interests as a cover for the importation of slaves. These camels, having served their purpose, were turned loose to range the coastal country and were killed off by cattlemen. Meanwhile, Wayne had tested the camels' usefulness. A strong male loaded with 1,256 pounds of hay rose easily and walked off with the burden. Trips to San Antonio for supplies demonstrated that six camels could move as much freight as twelve horses in half the time, traverse muddy roads on which horses could not pull wagons, and climb mountain trails where no wheeled vehicle could roll.

The animals proved to be docile, except in the rutting season, but the army hostlers and wagon masters didn't like them and the camels' smell terrified the horses. Nevertheless, when the native drivers, in their colorful red coats and blue pants, rode into Houston, signaling their approach by the jingling of large bells suspended from the camels' necks, they created a sensation. People watched entranced as the camel drivers switched a camel's legs and the obedient beast kneeled and rose at the word of command. A Texas newspaper poet wrote in celebration of the exotic visitors in the columns of the *Indianola Bulletin* and a Miss Mary A. Shirkey of Victoria knitted a rather smelly pair of socks for President Pierce from the pile of a government camel. For this courtesy she received appropriate thanks, and Major Wayne thought that perhaps camel hair would be a spinoff from the experiment that would have economic value. Secretary Davis, in his final report at the end of 1856, assured the president that the effectiveness of camels in the American West had been established.

John B. Floyd, who succeeded Jefferson Davis at the War Department, shared his predecessor's views on the adaptability of the ship of the desert to conditions on the plains, mountains, and deserts of the southwest. But he was not able to persuade Congress in 1859, or again in 1860, to increase the American equity in camels. Meanwhile other officers had made successful trials of the camel herd in survey-



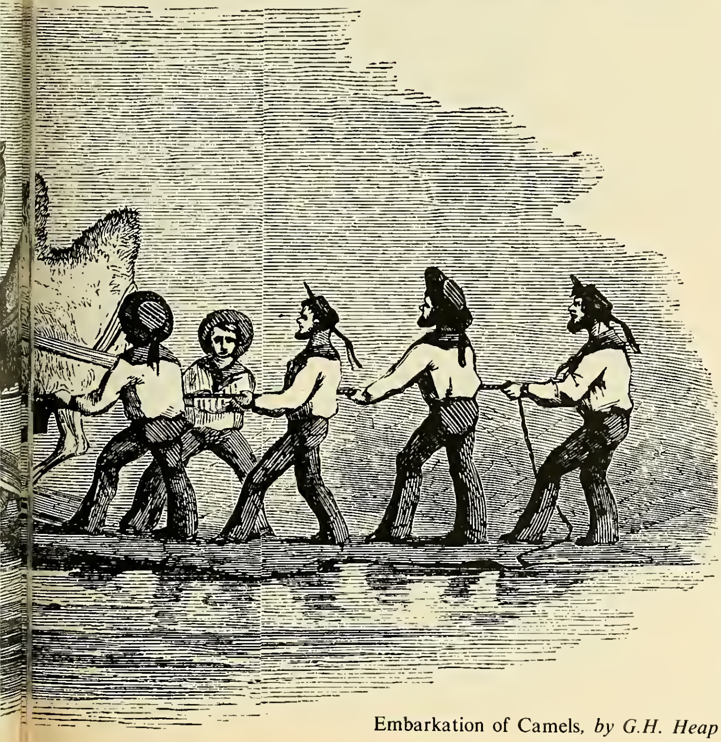
Senate Executive Document No. 62
34th Congress, 3rd Session

ing parties. Lt. Edward F. Beale in 1857 had thoroughly tested a portion of the camel herd while laying out the Great Wagon Road through Indian country. This expedition surveyed the route from Fort Defiance in New Mexico to the Colorado River or state line of California, near the thirty-fifth parallel.

The lieutenant was the only man in the party who liked and understood camels. There had been a contretemps involving the native drivers who had come to America with the animals. The drivers had refused to budge from their headquarters at San Antonio, "alleging that they had been badly treated by the government," Beale wrote in his journal, "not having received the pay due them since January . . . the appropriation having been exhausted, no one is authorized to pay them," although they "have performed their duties very faithfully." Beale had a good eye for the natural beauty of the landscape they passed through and for a picturesque scene. The camels, led by old Mahomet, stretched out in a "long line of . . . grave and patient followers"; as they wound down the slope of a bluff they made "a picture worthy of the pen of a great artist."

Beale found that it was indeed true that the camels could go without water for two days or more without difficulty and noted that, ironically, it was their task to carry breakers of water to sustain the horses and mules. As for forage, they actually preferred bitter herbs and dry shrubs such as greasewood, the low-growing brush prevalent in dry valleys, or the screw bean, a form of mesquite, to the finest grama grass. To the Oriental ruminants, the prickly pear, spiny mesquite, even the maguey with its tough blades and sharp needles were consumed with relish as "camel clover."

According to Alex E. Sweet and J. Armoy Knox, two adventurous newspapermen, sharp observers with a sense of humor, the camel was a voracious feeder, with a strong preference for cactus leaves and mesquite pods, "but he does not confine himself altogether to a vegetable diet. When opportunity offers, he will reach up after the glass insulators of a lightning-rod or telegraph pole, and conceal them in his commissary, or he will stand by the hour meekly chewing up a wagon-sheet, when he cannot get a chance to eat the well-rope or a wheelbarrow."



Embarkation of Camels, *by G.H. Heap*

At the beginning of the Civil War the government camels were kept in a camel pen with sixteen-foot walls of stone, concrete, adobe, and timber, at Val Verde. This military post, sixty miles southwest of San Antonio near the headwaters of a tributary of the Guadalupe River and three miles from Bandera Pass, was the permanent station of the Texas camels. Lieutenant Beale's camels remained in California, unused. An attempt was made to employ the beasts in carrying the mail, but post office officials, ignorant of the management of camels and not inclined to learn, successfully resisted the plan. During the war the California herd was sold to an entrepreneur who found buyers in circuses and zoological gardens.

In 1861 the Confederate forces seized the camels at Val Verde but the southern government was too overextended by the war to carry the experiment forward with vigor. The Confederate post office department used some of the camels; other animals carried cotton, a bale swung on each side, moving the cotton to Matamoras and returning with salt from Salt Lakes. Still others were turned loose and became wanderers. No particular care was taken to prevent their escape and they came to be regarded as a nuisance. Three were caught in Arkansas by Union soldiers. Another strayed west through Bandera Pass. When the camels were repossessed by the United States, the War Department no longer had the resources for carrying on the camel experiment. The railroads were coming and the whole idea of camels suffered from its close association with Jefferson Davis, officially a traitor for becoming the Confederate president. (Davis's citizenship was restored only two years ago, in 1978, when President Carter signed the necessary legislation.)

During the Reconstruction years the animals at the Val Verde station were scattered. Some ended up in the Ringling Brothers circus and camel driver Long Tom went with them. The government turned others loose in Arizona where they thrived and multiplied. In 1870 a Nevada salt miner rounded up twenty-five in the Carson River district. The camels must have been numerous and troublesome in Nevada because the state legislature passed a law in 1875 making it a misdemeanor for the owner of "any camel or camels, dromedary or dromedaries

Now You Can Beat Inflation...

Invest in Rare U.S. Stamps!

Now you can outrun inflation and thrive on recession by participating in America's largest Rare U.S. Stamp Investment Society -First National Investors.

During the last five years rare U.S. stamps have been spiraling up at unbelievable rates -in 1979 alone U.S. stamp values have achieved a growth rate of 23.6%... outpacing inflation, diamonds, common stocks, high grade corporate bonds and single family housing values.

These impressive increases in value are the result of a rapidly increasing demand by professional stamp collectors and investors for the absolutely fixed supply of existing rare U.S. stamps. The supply of U.S. stamps produced in the 19th and early 20th centuries can never be increased.

Competition for the higher quality stamps of the past will only serve to drive their prices even higher. The ever-increasing demand for quality United States stamps has created a seller's market.

Rare U.S. Stamp Investments are completely private. A large investment can be stored safely in a small place-like an album or safe deposit box. No one ever needs to know you are investing in stamps. Our members' names are held strictly confidential.

Now, our professional service makes investing in rare U.S. stamps simple. You can participate with confidence in the rapidly rising values of rare U.S. stamps. For as little as $20 per month, FNI will help you build a rare stamp investment portfolio on a regular monthly basis. As a subscriber to Rare U.S. Stamp Investments, you are given the opportunity to capitalize on the experience and know-how of our stamp experts.

Each stamp is accompanied by a certificate of authenticity and a full money-back guarantee. And each stamp is chosen not only for its beauty, but its investment value. Rare stamps offer one of the last truly great investment opportunities in America today.

. . . knowingly and willfully" to permit their property to run at large "on or about the public highways of the state of Nevada."

Sightings of government camels and their descendants continued for the rest of the nineteenth century. They were seen ranging with cattle, and often a lumbering old beast showed up at a roundup. One came out of a mesquite bush at Refugio at milking time, a grotesque figure. "The cow," Chris Emmet wrote in *Texas Camel Tales*, "departed without ceremony." A herd was seen near Oatman's Flat on the Gila River in 1875. A decade later a little boy of five whose father was commander of the army garrison at Fort Selden, New Mexico, saw an extraordinary sight that he recollected later in life. "One day a curious and frightening animal with a blobbish head, long and curving neck, and shambling legs, moseyed out of the Jornada [Jornada del Muerto] . . . the animal was . . . one of the old army camels." The little boy was Gen. Douglas MacArthur.

In 1890, or maybe it was 1891, nine camels roaming on the western edge of Death Valley, California, appeared, silhouetted against the sky, before the eyes of two gold miners who thought they were seeing ghosts. The miners, Shep Searcy and Charlie Fisher, were lying down at the time, trying to drink from a mud puddle, when Shep said, "Do you see what I see?"

Fisher answered, "I do not know what you see, Shep, but it looks like Barnum's circus to me."

Then the camels sniffed, snorted, and ran away. When the miners reported their experience at the next town, people thought they were crazy.

"The attempt to make use of camels might have succeeded under different conditions," wrote the late Walter L. Fleming, dean of Vanderbilt University and an authority on the experiment in all of its ramifications. The operation lost its strongest advocate when Jefferson Davis left the War Department. Major Wayne, the camels' best friend, who had both theoretical and practical knowledge of the animals, had joined the Confederate army in 1860. Beale, who once drove a hundred miles in a sulky drawn by a team of camels with whom he carried on a conversation in Syrian, was discouraged by officialdom from pursuing his experiments. Finally the rapid expansion of the rail network made transportation by beasts of burden a picturesque but historical anachronism.

Thus endeth a story of the American West, filled with desert dust and camel musk. The camel drivers, strangers in a strange land, lost in the alien culture of the Anglo-Americans, deserve a last word. Greek George, a sturdy man with a Homeric beard, became George Allen and died an old man in Whittier, California, September 2, 1915. Long Tom went with the Ringling Brothers circus, as mentioned earlier. Hi-Jolly wandered for decades over the desert as a prospector and was reported to have died in Arizona in 1902. But J.W. Walker, who had herded camels at Val Verde, told a different story. He said that some fellows saw an old camel browsing near a town where they had gone "to get 'wet up' a little" at a saloon. Standing at the bar they told of seeing the camel. A dark-skinned man standing near them asked quietly, "Boys, where is that old camel?" After they told him, he pulled his hat down hard and walked off in the direction that they indicated. The next day, cowmen hunting strays found Hi-Jolly and the camel lying dead. Hi-Jolly's arms were around the animal's neck.

"I don't suppose this story is true," Walker recalled, "but that's the way I'm always going to believe old Hi-Jolly died."

# Celestial Events

by Thomas D. Nicholson

**Sun and Moon** Since the moon was full on the last day of April, it becomes a morning object on May 1, waning in phase, rising after dark, and remaining in the sky past dawn. Last-quarter is on May 7, new moon on the 14th. It becomes an evening object again when the young crescent appears at sundown on the 16th or 17th, reaching first-quarter on the 21st and full on the 29th. Phases in June are: last-quarter on the 5th, new moon on the 12th, first-quarter on the 20th, full on the 28th. Perigee moon (nearest the earth) is on May 12, June 4, and June 30; apogee moon (farthest from the earth) is on May 21 and June 18.

**Stars and Planets** Bright planets continue to dominate the evening sky: Venus in the west; Jupiter, Mars, and Saturn (and the nearby bright star Regulus) in the east. But an experienced observer will see signs that they are past their prime. Venus is high and bright at sundown, better than it has been all year. After mid-May, however, it will be noticeably lower and will set earlier on each successive night. Its brightness will begin to fade toward the end of May. Jupiter, Mars, and Saturn are conspicuous in Leo, along with Regulus, its brightest star. They will be well up in the south at dusk, setting in the west a few hours past midnight. Jupiter and Mars are very close to Regulus in early May, and Mars is still quite bright. They will present an impressive gathering of bright objects. But the configuration decays after midmonth as Mars moves swiftly away to the east (left) and dims. Mercury moves from Pisces, through Aries and Taurus, into Gemini; Venus drifts from Taurus into Gemini before mid-May; Jupiter, Mars, and Saturn remain in Leo, Uranus in Libra, Neptune in Ophiuchus, and Pluto in Bootes.

May 4: Mars and Jupiter are in conjunction. Mars now moves from west to east (right to left) past Jupiter. The Eta Aquarid meteor shower (20 meteors per hour) reaches maximum.

May 8: Venus is at greatest brilliancy in the evening sky.

May 13: Mercury, in superior conjunction, becomes an evening star.

May 15: The moon occults (covers) Aldebaran over North America at about 9:00 A.M., EST.

May 16: The moon is near Venus tonight.

May 21–23: The moon offers an exceptional opportunity to identify Regulus, Jupiter, Mars, and Saturn as it moves past each in turn.

May 23: Saturn resumes its direct (easterly) motion.

May 24: Venus begins its retrograde (westerly) motion.

May 31–June 1: Mercury and Venus are in conjunction at 1:00 P.M., EST, on both evenings. Mercury will appear as a bright object very close to Venus.

June 11: The moon occults Aldebaran over North America at about 7:00 P.M., EST.

June 14: Mercury, at greatest easterly elongation, is well placed as an evening star.

June 15: Venus, in inferior conjunction, becomes a morning star.

**Evening Star Map** To identify stars in the northern sky, hold the map in front of you with north at the bottom and match the stars on the lower half of the map with those in the sky. When you face the other directions, roll the map to bring the corresponding compass point (east, south, or west) to the bottom, and match the stars in the sky with those on the lower half of the map. The map represents the sky at about 11–12 P.M. on May 1; 10–11 P.M. on May 15; 9–10 P.M. on May 31; and 8–9 P.M. on June 15. It shows only planets and moon phases above the horizon at those times.

KNOW
THE
STARS

**WHAT STAR IS THAT?**

The ISO-VUE STAR POINTER will tell you. Just *point* it at any star or constellation to find out its name!

It will also *find* any star, planet, or constellation for you, too. And it *points* to it, and holds up a map of it at just the right angle for your time and place—anywhere, any time. And much, much more.

Complete instructions, sky maps and Star Cards for the 32 major constellations. Satisfaction guaranteed, or full refund. $7.95 + 95¢ postage. ISO-VUE 6306 K Baylor Dr., Tucson, Arizona 85710.

**A MARVELOUS GIFT FOR A SCIENCE-MINDED FRIEND!**

*For the sixth year, we invite adventurous travelers to join us on our fascinating*

Naturalist's Safari in Rajasthan

with a visit to Tiger Haven in Uttar Pradesh and, including attendance at the Pushkar camel fair by full moon:

NOVEMBER 14 TO DECEMBER 5, 1980

This original tour of Northern India is designed for people whose interests lie in watching and photographing animals and birds in their natural surroundings, riding elephants and walking in unspoiled countryside. Agra and the great palace cities of chivalric Rajasthan—Jaipur, Jodhpur and Udaipur—are also visited.

The tour offers a great variety of wonderful scenery, as well as the opportunity of studying flora from Himalayan foothills to the desert. In the cities we stay in deluxe hotels; accommodations on safari are at lodges in lovely wildlife parks and in the sandstone hills of the Rajasthan desert.

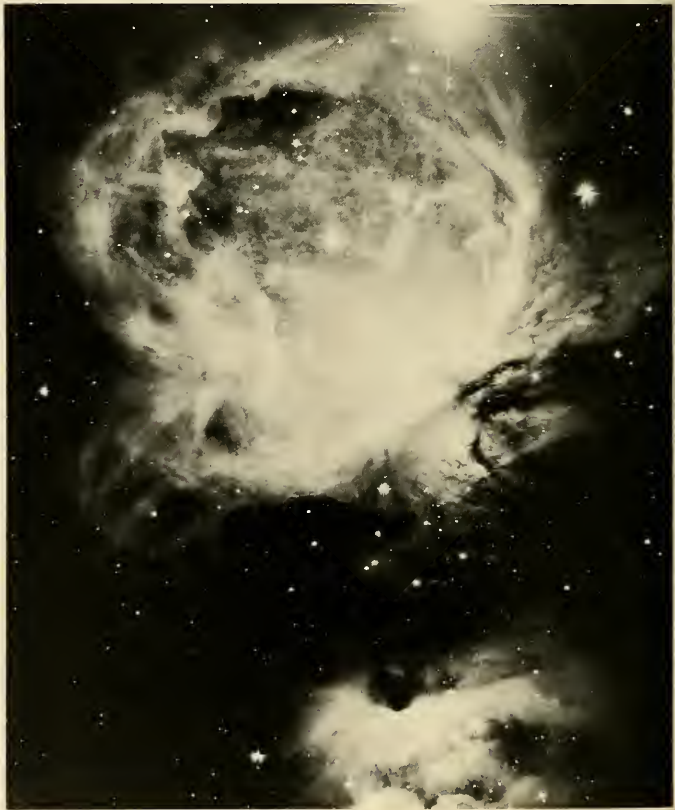
# The Orion Nebula

*Why is this well-known object expanding in only one direction?*

**by Stephen P. Maran**

Anyone who has leafed through an illustrated book on astronomy has seen a picture of the Great Nebula in Orion, also known as M42. The brightest and perhaps most spectacular nebula in the heavens, it is a cloud of hot, glowing gas. Located in Orion's Sword, M42 is about 1,500 light-years from the earth. Even when seen through an amateur astronomer's small telescope, the nebula is a superb sight. At its heart are four hot young stars, known as the Trapezium for their simple geometric pattern.

Orion itself is a striking constellation. It contains many bright stars and straddles the celestial equator, so it is at least partially visible from every spot on earth. Thus, it was natural for Galileo, in 1609, to turn his new tele-



*The Great Nebula in Orion*

Lick Observatory

scope in Orion's direction. He scanned the region around the Sword and found that diffuse patches of the Milky Way were telescopically resolved into a myriad of tiny stars. And yet the Great Nebula, which must have been plainly visible, is not mentioned in Galileo's notes. Instead it was a French lawyer and astronomy buff, Nicholas-Claude Fabri de Peiresc, who discovered the nebula in 1610 with one of Galileo's own telescopes.

Peiresc's discovery was apparently overlooked or forgotten, and a Swiss astronomer, Cysatus, "discovered" M42 anew in about the year 1618. His report was well preserved (although at least one famed seventeenth-century astronomer was unaware of it), and a cursory inspection suggests that most modern accounts credit Cysatus rather than Peiresc with finding the Orion Nebula.

The noted astronomer who was ignorant of even Cysatus's "discovery" was Christian Huygens, a Dutch optics expert and clockmaker. As late as 1656, he too reported "discovering" the Orion Nebula. Huygens compared it to "an opening in the sky through which a brighter region was visible." His drawing of the nebula and those of later astronomers who studied it differed greatly from each other, leading to the suspicion that M42's shape might have changed. But the differences in the sketches of the nebula were the result of artistic license taken by the observers, who were confronted with the difficult task of drawing a telescopically viewed object of amorphous appearance while working in the darkened surroundings of an observatory.

The designation "M42" comes from the serial number of the Orion Nebula in a catalog of nebulae and star clusters published by the French astronomer Messier in 1784. By the late eight-

"I ONLY SPEAK ENGLISH. BUT, WITH MY CRAIG TRANSLATOR, I CAN MAKE MYSELF UNDERSTOOD TO OVER 2 BILLION PEOPLE."

*Jim McKay*

Even world traveler Jim McKay needs a little help now and then making himself understood. That's why he carries the Craig Translator and Information Center.

It's his communication key in fifteen languages: English,* French,* Spanish,* German,* Italian,* Japanese,* Dutch,* Arabic, Russian, Chinese, Danish, Norwegian,* Portuguese, Swedish, and Finnish. He just snaps in a tiny language capsule and has the world at his fingertips. And he can use three different languages simultaneously, translating from one to another at the touch of a button.

2000 WORDS

We've doubled capacity of the most popular capsules to approximately 2000 words each, plus 49 common phrases. A remarkable phonetics capsule* shows you how to pronounce words or phrases in French, German, Spanish and Italian. Japanese, Russian, Chinese, and Arabic are displayed phonetically.

We've added information capsules: a Nutrition Guide and Calorie Counter,* a Bar and Wine Guide,* and Business Terms, even a Word Game capsule including Anagrams and Hangman, and a Las Vegas capsule that lets you play Black Jack without losing a penny.

Visit your Craig dealer and try out the Craig Translator and Information Center. And when you're traveling, you'll never find yourself at a loss for words.

*These capsules are available now. The others will be available shortly.

eenth century, it was known that some of these "nebulae" had spiral-shaped features. Today we know that such objects are *not* gaseous nebulae like M42, but are spiral galaxies, island universes far larger and more distant than the Orion Nebula. However, this modern distinction had not been made when, in the 1780s (and on subsequent occasions well into the nineteenth century), much effort was spent in the attempt to discern spiral features in the Orion Nebula. Some astronomers did "find" spiral forms in the Great Nebula, just as some astronomers claimed to "see" canals on Mars. But in fact there are none.

By the 1950s, it was known that the Orion Nebula is an H II region, meaning a cloud of electrically charged, or ionized, hydrogen and other gases that are heated by ultraviolet radiation. That radiation also excites the gases electrically, causing them to glow.

Most of the radiation that excites the gases in the Orion Nebula comes from the hottest of the four Trapezium stars. Ultraviolet radiation streams out from this star equally in all directions, heating and exciting the surrounding gas. This simple explanation can be found in many texts, but the actual situation is more complex.

Since a hot, unconfined gas will expand, the above simple theory would lead us to expect that the hot gas of the Orion Nebula is flowing outward. Such is the case on the side of the nebula that faces the earth, as shown by the presence of blue-shifted emission lines in the spectrum of the nebula. These shifts, caused by the Doppler effect, indicate that gas is indeed streaming toward us. By the same token, the gas on the far side of the nebula should be moving away from us and hence should produce red-shifted spectral lines. But lines of the latter type are not present.

There is known to be some interstellar dust (microscopic rock particles) in the Orion Nebula. This finding suggested the following explanation for the lack of red-shifted lines from the far side of M42: there might be more dust in the far half of the nebula than in the near half, dimming the light from the far side and making the postulated red-shifted lines invisible from the earth. This explanation, however, has been ruled out by observations with a radiotelescope.

Although visible light is absorbed by interstellar dust, radio waves are not. Observations of a radio wave emission

*For the fourth year, we offer a small group of adventurers a unique travel experience:*
**The Great White Bears**
**OCTOBER 16 TO 21, 1980**
Each year, in late October, hundreds of 1000 pound polar bears migrate towards the shore of Canada's vast Hudson Bay and wait there for the coming of the winter sea ice.
From our comfortable Churchill base we again make forays to see and photograph the remarkable and stirring sight of these wild carnivores roaming free.
The unique expedition is limited to twelve members plus our team of highly experienced leaders and staff, involves the hire of helicopters and hardy guides for the group's protection, and is unavoidably costly.

line of hydrogen, made in the 1960s, thus were capable of surveying the entire Orion Nebula, whether or not there is much dust in its far half. Nevertheless, those measurements failed to turn up the anticipated red-shifted emission. Instead, they revealed the same pattern of motion in the nebula that had already been found in the visible-light spectrum: the gas was expanding toward the earth, but not away. This is not just a simple case of the nebula as a whole moving toward us (as opposed to its expanding in size), for in that case we would observe identical blue shifts at all positions on it. The nebula really *is* expanding, but only in one direction.

The gaseous outward flow of the Orion Nebula is not uniform and some of the nebular gas does not even participate measurably in the flow. An important clue to the conditions of the flow came in a 1966 study by James B. Kaler, an expert on nebulae at the University of Illinois Observatory in Champaign-Urbana. He examined the radial velocity, that is, the motion along the line of sight from the earth, as revealed by Doppler shifts, of seven types of ions in the Orion Nebula. (An ion is an electrically charged atom that has lost one or more of its electrons; in the case of this nebula, as a result of exposure to ultraviolet radiation.)

Kaler discovered that although the velocities of the various ions in the Orion Nebula differ greatly, they differ in a systematic way. The cooler ions are moving at about the same speed as the Trapezium stars. In effect, these ions constitute a gas that is nearly at rest with respect to the center of the nebula. This does not mean that the cool gas is at the center; being closest to the hot, radiating stars, the center should be hottest. However, Kaler found that the hottest ions are moving rapidly toward the earth.

If the Orion Nebula is expanding toward us but not away, then something must be confining the rear hemisphere of the nebula. The discovery of radio emission from formaldehyde and other complex molecules in the direction of the nebula, made during the early 1970s, revealed what the obstacle must be. These molecules can only exist in a very cool gas, shrouded from disruptive ultraviolet light by thick dust. The radio observations indicated that a large dark cloud, more massive, denser, colder, and dustier than the Orion Nebula, lies just behind it. The thin expanding gases of the nebula cannot penetrate the denser medium of that molecular cloud. Hence they do not flow toward it but only toward us.

Infrared telescopes reveal that new stars are forming behind the Orion Nebula, in the thick gas and dust of the Orion molecular cloud. As the new stars evolve, their surface temperatures will increase and they will emit large amounts of visible and ultraviolet light. This radiation will evaporate some of the dust around them and will heat and ionize the gas in their vicinity, causing it to glow. The process, astronomers now believe, has already taken place in the Orion Nebula; the Trapezium stars that formed at the edge of the dark cloud behind the nebula have heated their surroundings to form a glowing region, or "blister" in the jargon of astrophysics, around them. The blister is the Orion Nebula and its expanding gases flow toward us; at its rear, the warm blister is slowly eating away at the boundary of the mother cloud, warming the adjacent cool material in the manner of a spreading infection.

The freshly warmed material at the back boundary of the Orion Nebula probably corresponds to the cooler gas found by Kaler that is not perceptibly expanding. As that material is exposed to more ultraviolet light and is heated further, it joins the rapid flow away from the dense cloud, like steam issuing from a kettle. A few isolated clumps of dark material do exist on the near-side boundary of the Orion Nebula. The gas at the rear of these clumps faces the Trapezium and hence is slowly warming up. As it warms, it expands away from the dark clumps and thus flows *toward* the Trapezium and away from the earth. This limited flow away from us and toward the center of the Orion Nebula is an exception that confirms our understanding of what is happening in the nebula and why.

The astronomers of earlier times could only explore the Orion Nebula in visible light; nevertheless, they found it an impressive object. Radio and infrared telescopes now verify that a previously unsuspected dark molecular cloud is actually the principal object in the Sword of Orion and the parent body of the Great Nebula itself.

"An eternally fascinating subject."
–DESMOND MORRIS, from the Introduction

THE ANIMAL FAMILY

Dr. Philip Whitfield, Consultant Editor
Illustrated by Richard Orr and Michael Woods

This vivid and beautifully illustrated book presents the miracle of animal reproduction in clear and comprehensive detail. Over a period of centuries, animals have evolved rituals for survival that perfectly fit their ecologic niche. This book is "all about things like courtship, mating, home-building, territory, birth and the caring for the young....The profuse illustrations...are not only beautiful pen-and-ink work, they illuminate as no photographs could."–*Los Angeles Times.* With over 500 two-color illustrations. $19.95

NORTON
W.W. Norton & Company, Inc.
500 Fifth Avenue, New York 10036

"A gorgeous, colorful, and fascinating celebration of the United States."
– *Washington Star*

In this broad and brilliantly illustrated book, authors from many fields explore the evolution and present condition of the American environment. By means of landscapes from the Smithsonian's galleries, unprecedented color photography, and dramatic diagrams, the face of the nation appears here as it has never been shown before – historically bountiful, scientifically challenging, and culturally unifying. 400 photos, many of them in color, and drawings. $21.95

# After Audubon

**by Peter Farb**

On the Road with John James Audubon, by Mary Durant and Michael Harwood. *Dodd, Mead and Company, $19.95; 576 pp., illus.*

Following in the footsteps of a noted traveler—reconstructing a lost world and illuminating it with modern scientific knowledge—is an inherently fascinating genre that in recent years has resulted in books retracing the paths of Homer, Saint Paul, Darwin, and others, yet it has produced no very memorable book—until this one. Durant and Harwood have given us an eminently readable, endlessly fascinating journal that retraces Audubon's comings and goings from his arrival in the United States in 1803 to his death in northern Manhattan Island in 1843. They have achieved this partly because they have combined the "in-the-footsteps-of" genre with another that is best exemplified by Roger Tory Peterson and James Fisher's *Wild America* (1955). This second type gives the follower of footsteps a partner, with the result that two knowledgeable travelers can compare notes, offer different points of view, and in general enliven the inevitable dull stretches of the journey. Durant and Harwood are invariably informative, enthusiastic, and cheerful. They have done their homework in reading all of Audubon's writings and many works about the American land, they know their ecology and natural history, and they are sensitive observers of human life as well.

The pattern of the book is first, to offer for each place a brief quotation from Audubon's writings, then follow with a modern description, additional facts, interpretation, a dialogue between the authors, and sometimes their dispute with Audubon. This pattern is invariable and might have become boring in such a long book, but it gains flexibility through the liveliness of the writing, the freshness of the authors' impressions, and the occasional badinage between them. Potential dull spots are enlivened with humor, as when Durant and Harwood become impatient with the precious bird names given streets in Louisville, Kentucky, and compete in making up some of their own: Rue Cuckoo, Rail Road, Tern Pike. The writing is often imaginative, as in this description of the mockingbird: "The mocker's song puts Michael in mind of Latin declensions. It speaks to me of embroidery stitches. The song is like a sampler—rows of elaborate stitches, no two rows alike, and each row sewn in bright silk flosses with a gold needle."

To write their book, Durant and Harwood compressed Audubon's four decades of travel into a little more than a year of their own traveling. They logged some 35,000 miles—by automobile, Mississippi River towboat, cutter, ferry, and their own legs—from Labrador to the Dry Tortugas off southern Florida and west to Montana and Texas (Audubon never accomplished his desire to cross the Rockies to the West Coast). They explored the rivers and creeks, bayous, shores, forests, and prairies that Audubon had known, and also the once-wild lands that are now the slums of large cities.

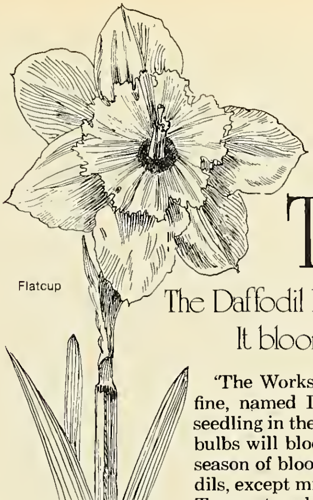
As this issue went to press, *Natural History* was saddened to learn of the death of Peter Farb on April 8, 1980.

Their travels began in Mill Grove, Pennsylvania, where Audubon had arrived in 1803, age eighteen, the illegit-

# Books in Review

United States to escape conscription into the French army. From there they inquire into Audubon's early mercantile businesses in Louisville and Henderson, Kentucky, search out descendants of Audubon's storekeeping partner in Saint Genevieve, Missouri, trace his route down the Mississippi to Saint Francisville, Louisiana (where Audubon was to stay for eight years), following him even when he was himself retracing the footsteps of Alexander Wilson, then on to South Carolina and Florida, northward to Canada, to the Missouri River—in short, searching out virtually every place, even those seemingly of little consequence, that Audubon mentioned in his extensive writings.

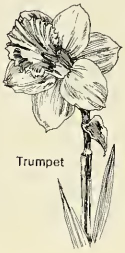
It is all here, almost every move Audubon made, down to the completion of the *Birds of America*—called by his contemporary Baron Cuvier "the most important monument which has been erected by Art to Nature"—and the near completion of the *Viviparous Quadrupeds of North America.* The story ends with Audubon's death, the subsequent impoverishment and hard luck of his family, the rats devouring the unsold copies of the *Ornithological Biography*, the copper plates of the bird engravings sold as scrap metal, and the sale of the original paintings for a mere $2,000 to the New York Historical Society (which did not fully exhibit them until this past decade). The authors' journey is arduous, but we rarely grow weary accompanying them, in large part because they manage at every stop to evoke the time past, to supply us with interesting facts, and to guide us through the many inconsistencies in Audubon's



Flatcup

Poetaz

Triandrus



Trumpet

The Works®

The Daffodil Mixture That Is Really a Mixture.
It blooms for weeks and lasts a lifetime.

'The Works' is unique because it is made up of *only* fine, named Daffodil varieties of recent origin, not a seedling in the lot. Each of these top-grade, double-nosed bulbs will bloom the first year. 'The Works' has a long season of bloom because it contains all classes of Daffodils, except miniatures, and is carefully balanced among Trumpets, which have yellow, golden, bi-color, or pink blossoms; Flatcups in great variety, with flaring petals and heavily-ruffled flat cups; members of the Poetaz group, some of them doubles; Cyclamineus Hybrids having shorter stems holding smaller flowers; and Triandrus Hybrids with clusters of bloom on each stalk. This is a delightfully informal way to naturalize Daffodils and it may amaze you to see so many kinds you've never seen in bloom — unless you've been to Holland in the spring.

Daffodils, as you may know, are *nearly indestructible* perennials — they seem to last as long as Peonies, which is a lifetime. They bloom sensationally the first spring, and grow more beautiful each year thereafter. A planting of Daffodils naturalized here 45 years ago still blooms gloriously, but is now more extensive, for the bulbs are great self-propagators. Pick blooms for indoor bouquets. What more could one ask?

You wouldn't expect a mixture of named-variety Daffodils, double-nosed or top-grade, to sell for less than $43.00 a hundred, and it doesn't. But $43.00 is *less* than the price of other good mixtures. 'The Works' is sold only by the 100 (for 500 to one address deduct 5%; for 1,000 deduct 10%). For prepaid handling and delivery please add 10% east of the Mississippi; 15% for Gulf states and west of The River (Connecticut residents add sales tax). Bulbs will be shipped in time for fall planting.

Order 'The Works' from this advertisement. With it you will receive, without charge, the 1980 Fall Edition of *The Garden Book* and a year's subscription to our nationally-known Gardening Publications Service in 1981. This consists of the Spring and Fall editions of *The Garden Book*, our catalogue which is *really* a garden book, and three editions of NOTES, a valuable reminder publication. The Service is sold by subscription for $5.00 a year, but is sent without charge to active customers.

Please order now. 'The Works' sells out every year and cannot be re-shipped from Holland. — A. Pettingill

work. They provide, for example, a very helpful key to the fanciful names Audubon often gave various birds—such as Brown Eagle (he probably meant both the immature bald eagle and the adult golden), Dun Diver (the female common merganser), French Mocking Bird (brown thrasher), and Irish Goose (double-crested cormorant).

So much research and traveling hither and yon on the part of the authors would hardly have been worth the trouble were Audubon not a complex and interesting personality. Everyone knows of the prodigies he performed for conservation and his pioneering efforts in systematically studying the fauna of a continent. But not generally advertised by the local, state, and national Audubon societies that have taken his name are his less praiseworthy traits: he was a habitual liar (he claimed, to mention just one fabrication, to have studied with the great French artist Jacques Louis David), a plagiarist (a shameless pirate of bird illustrations by others), a poseur (on a sales trip to England, he smeared his hair with bear grease and dressed up in frontier costumes he never wore in America), a butcher (he blasted for sport many more birds than he needed for copying or for food), and an irresponsible family man (leaving wife and brood to fend for themselves).

I have always considered particularly distasteful Audubon's opportunism regarding native Americans, and I am glad that the authors do not gloss over these facts. The Audubon who had expressed sorrow at the plight of the Seminoles, the forced relocation of the Cherokees, the rapid disappearance of the Indians of Labrador made a complete reversal after being taken to task as an Indian lover. He was soon to label the Indians "savages," even blaming them for dying in such great numbers from the white man's smallpox. Nor do the authors avoid pointing out that he was a dandy, a salesman, a merchant who developed his passion for natural history only when his life was considerably more than half over. They are skeptical where skepticism is needed, as when they give the lie to some of Audubon's outrageous claims; they touch on Audubon's shabby treatment of Alexander Wilson; they deplore his gulling of the naturalist Constantine Rafinesque with fanciful descriptions of birds and fishes, which, published in scientific journals, must have set American natural history

The Prehistory of the Ayacucho Basin Peru

The Non-Ceramic Artifacts

A team of specialists, with Richard MacNeish as principal investigator, now commences publication of its findings after almost a decade of research in the Ayacucho Basin in Peru, a pristine nuclear site. Four subsequent volumes will cover the environment, subsistence, excavation chronology, and way of life of sedentary and non-sedentary people. **$45.00**

back a decade. The outrageous myths Audubon created to hide his bastardy are also discussed: he invented a birthplace for himself in a Louisiana mansion (instead of the actual trader's house on the island of Santo Domingo), an aristocratic Spanish mother (instead of the real French chambermaid), and he even confided to his family and close friends that he was really the Lost Dauphin, that missing offspring of Louis XVI and Marie Antoinette.

As husband and wife, Durant and Harwood are interested in the relations between Audubon and his extraordinarily indulgent wife, Lucy. Early in the book, Mary Durant puts under scrutiny a seemingly enthusiastic letter by Lucy about Louisville, the first place to which she accompanied Audubon when he left Mill Grove to become a storekeeper. Lucy praises the gardens, the welcome given them by the inhabitants, and the privacy they enjoy. Michael Harwood takes Lucy at her word, but Mary Durant reads "negatives, spoken and unspoken, in every line." Durant points out that Louisville was then known as the Graveyard of the Ohio because of the prevalence of diseases, its main street was known as the Slough of Despond because of the muddy hog pens and wastes from slaughterhouses, and the neighbors who allowed them privacy were prostitutes, gamblers, and drunkards. Later in the book, Durant recalls Lucy's often quoted statement, "I have a rival in every bird"—but believes that things were much more complex than that. Durant and Harwood speculate about Lucy's reactions to her vain, impudent, braggart husband who made foolish investments in his hope to get rich quick. They suggest that Audubon may not have remained celibate on his travels, for he alludes to his flirtations and to the pleasures of what he calls "horizontal patterns." About halfway through the book, Durant decides that she is not fond of Lucy: "I get the strong impression that she was among those self-righteous people who never let you forget just how noble they have been."

I have dwelt on the less pleasant aspects of Audubon's life not because this is a muckraking book or a psychobiography but rather to impress on you that this book is much more than a litany of places and sights and that the authors, while mindful of the contributions of Audubon, do not worship blindly. By the end of the book, following the footsteps of Audubon has become for Durant and Harwood not just an exploration into the heart of a continent but also a journey into the heart of Audubon. Concludes Mary Durant:

> I realize for the first time that I know more about John James Audubon than I do about anyone else in the world, except myself. . . . I've read his journals, his mail, his anecdotes, his essays. We've stood in his tracks, tramped his woods and marshes, his riverbanks and seashores, climbed his hills, seen his vistas, slept under his skies and his moon. We have followed him down the arches of the years, and this moment, at his gravesite, is the day of his death.

Mary Durant writes that her eyes then fill with tears—and such trusted companions have the authors become that we don't find anything sentimental about it at all.

*Peter Farb's newest book,* Consuming Passions; The Anthropology of Eating, *will be published in September by Houghton Mifflin.*

The Fantastic Vacuum Engine

**The Flame Eater**

*For*
- ***Hobbyists***
- ***Students***
- ***Collectors***
- ***Experimenters***

With a slight twist of the flywheel, the engine roars to life. The alcohol flame dances furiously and a lance of fire stabs through the rapidly working valve. The exhaust-like popping coupled with the clattering of the valve assembly causes a pleasant commotion that is music to the ears of those that enjoy the mechanical marvels of man. This is the exciting "Vacuum Engine," with a history that goes back to the early 1700's. It is the ultimate in craftsmanship, function and beauty of design.

The Flame Eater measures 6″x 8½″ and comes with its own alcohol burner. Completely assembled, factory-tested and ready to fascinate you and your audiences with speeds up to 1,000 RPM.

# Additional Reading

**Mackinac Island** (p. 34)

*Silent Spring*, by Rachel Carson (New York: Fawcett World Library, 1978), is a compelling introduction to the many ways humankind has altered and damaged the environment through the use of chemicals. Robert van den Bosch's article "The Melancholy Addiction of Ol' King Cotton" (*Natural History*, December 1971, pp. 86–91) discusses the disastrous effects of the heavy use of insecticides to control insect predation on the cotton plant. In *The Pesticide Conspiracy* (New York: Doubleday and Co., 1978), van den Bosch further explains how pesticides kill more than pests and how insects adapt to poisons. R. L. Rudd discusses pesticides in the food chain and the fate of pesticides in the environment in *Pesticides and the Living Landscape* (Madison: University of Wisconsin Press, 1964). "The Unforeseen International Ecologic Boomerang," edited by Taghi Farvar and John Milton (*Natural History*, February 1969, pp. 41–72), presents reports on the effects new technologies have had on the environments of underdeveloped countries. "Natural Decline of a Pine Needle Scale (*Chionaspis pinifoliae [Fitch]*), Outbreak at South Lake Tahoe, California, Following Cessation of Adult Mosquito Control with Malathion," by R. F. Luck and D. L. Dahlsten (*Ecology*, vol. 56, pp. 893–904), is a specific account of the disruption of the balance of nature by a pesticide. *The Theory and Practice of Biological Control*, edited by C.B. Huffaker and P.S. Messenger (New York: Academic Press, 1977), proposes economically and ecologically sound systems of pest control and discusses the philosophy, theory, basic biology, and ecology of conventional biological control. An older collection of articles on insect problems in agriculture is *Introduction to Insect Pest Management*, edited by Robert L. Metcalf and William Luckmann (New York: J. Wiley and Sons, 1975). *Biological Control by Natural Enemies*, by Paul Debach (New York: Cambridge University Press, 1974), is an undergraduate-level text. A soon-to-be-revised edition of *Perspectives in Urban Entomology*, edited by G. W. Frankie and C. S. Koehler (New York: Academic Press, 1978), one of the first books to examine the urban pest problem, will focus more on the social implications of urban entomology and will have further reports by Richard Merritt and Keith Kennedy on the Mackinac Island fly problem.

**Illinois River Turtles** (p. 42)

*Turtles of the United States*, by C.H. Ernst and R.W. Barbour (Lexington: University Press of Kentucky, 1972), generally treats life histories of United States turtles. An older account, covering seventy-nine species and subspecies, is Archie Carr's *Handbook of Turtles: The Turtles of the United States, Canada, and Baja California* (Ithaca: Cornell University Press, 1952). *Turtles: Perspectives and Research*, edited by Marion Harless and Henry Morlock (New York: J. Wiley and Sons, 1979), is a compilation of data from the most recent turtle research. *Turtles of the World*, by Peter Pritchard (Neptune: T.F.H. Publications, 1966), is a reference used by herpetologists. *River Ecology and Man*, edited by Ray T. Oglesby, Clarence A. Carlson, and James A. McCann (New York: Academic Press, 1972), includes the chapter "Man and the Illinois River," by W. C. Starrett. More specific information can be found in *Man's Effect on the Fish and Wildlife of the Illinois River*, by H. B. Mills, W. C. Starrett, and F. C. Bellrose (Urbana: Illinois Natural History Survey Biological Notes, no. 57), and *Amphibians and Reptiles of Illinois*, by Philip W. Smith (Illinois Natural History Survey Bulletin, vol. 28, art. 1).

**Bowhead Whales** (p. 52)

Not much has been published on Eskimo whaling. *Alaska Whales and Whaling*, a colorful issue of *Alaska Geographic* (vol. 5, no. 4, 1978), includes articles on "Early Native Whaling in Alaska" and "Modern Eskimo Whaling," along with others on kinds of whales, whale distribution, and the history of whaling. More on the history of whaling can be found in John R. Bockstoce's *Steam Whaling in the Western Arctic* (Seattle: University of Washington Press, 1978). *Thomas Welcome Roys: America's Pioneer of Modern Whaling* is a biography of the whaling captain whose steam-powered factory ship and winch-operated device to retrieve sunken whales greatly increased the whaler's ability to process the kill.This book, coauthored by Frederick P. Schmitt, Cornelis de Jong, and Frank H. Winter, will be published later this year by the University Press of Virginia. The conflict between cod fishermen and the endangered humpback whale is discussed in "The Humpback is Not Over the Hump," by Jon Lien and Bora Merdsoy, *Natural History*, June/July 1979. The "Additional Reading" column of that issue describes seven more whale references. For the story of the Eskimo walrus hunters of Little Diomede Island, see Fred Bruemmer's "Life on a Cold Rock" (*Natural History*, March 1977, pp. 54–65).

**Jupiter** (p. 62)

Two articles in *Science*, "Mission to Jupiter and Its Satellites" (June 1, 1979) and "Mission to Jupiter and Its Satellites: *Voyager 2*" (November 23, 1979), and the August 30, 1979, issue of *Nature*, entitled *Jupiter and Io: A Special Supplement*, offer a wealth of information on the *Voyager* missions. See the March, May, September, and October 1979 issues of *Astronomy* for many short, colorful articles on Jupiter and its moons. "Jupiter," by John H. Wolfe, appears with eleven other articles on the solar system in the September 1975 issue of *Scientific American*. In "The Meteorology of Jupiter" (*Scientific American*, March 1976, pp. 46–56), Andrew Ingersoll analyzes weather patterns on Jupiter as recorded by *Pioneer 10*. Isaac Asimov discusses early records of Jupiter and recent discoveries about atmosphere, composition, and the Great Red Spot in *Jupiter: The Largest Planet* (New York: Lothrop, Lee, and Shepard Co., 1976). *Moons and Planets: An Introduction to Planetary Science*, by William K. Hartmann (Belmont: Wadsworth Publishing Co., 1972), and Joseph Chamberlain's *Theory of Planetary Atmospheres: An Introduction to Their Physics and Chemistry* (Chicago: Academic Press, 1978) are college-level textbooks. A useful, al-

though dated, technical reference is the comprehensive *Jupiter: Studies of the Interior, Atmosphere, Magnetosphere, and Satellites*, edited by T. Gehrels (Tucson: University of Arizona Press, 1976). Jupiter's moons are featured in "What *Voyager* Saw: Jupiter's Dazzling Realm," by Rick Gore (*National Geographic*, January 1980, pp. 2–29). The 1979 edition of Robert Jastrow's *Red Giants and White Dwarfs* (New York: W. W. Norton), a general history of the universe, includes color photographs of Jupiter and its moons taken from *Voyager*. Starting in October 1980, the Public Broadcasting Service will present "Cosmos," a thirteen-part television series, written and narrated by Carl Sagan. The executive producer is Adrian Malone ("Ascent of Man," "Age of Uncertainty"), and episode six will be devoted to the *Voyager 1* and *2* missions to Jupiter and beyond.

**Camels** (p. 70)

Much of the information on the U.S. government's camel experiment is buried in monographs and official publications. Some data are scattered throughout books that may be more accessible than government publications. For books on Jefferson Davis, see the AMS Press reprint of *Jefferson Davis, Constitutionalist: His Letters, Papers and Speeches,* volume 2, edited by Dunbar Rowland and first published in 1923, and *Jefferson Davis: American Patriot 1808–1861*, volume 1, by Hudson Strode (New York: Harcourt, Brace and Co., 1955). Both volumes of Robert McElroy's *Jefferson Davis: The Unreal and the Real* (New York: Harper and Bros., 1937) were reprinted by Kraus Reprints (Millwood, 1969). Information on the United States camels can be found in Chris Emmett's *Texas Camel Tales* (Austin: Steck-Vaughn Co., 1932, repr. 1969) and in Lewis Burt Lesley's *Uncle Sam's Camels: The Journal of May Humphreys Stacey Supplemented by the Report of Edward Fitzgerald Beale (1857–1858)*, published by Harvard University Press, 1929. Jefferson Davis's own account of the experiment appeared in his 1857 *Report of the Secretary of War, Communicating, in Compliance with a Resolution of the Senate of February 2, 1857, Information Respecting the Purchase of Camels for the Purposes of Military Transportation* (Sen. Ex. Doc. No. 62).

WHISKEY

JACK DANIEL
SQUARE GLASS SET

Mr. Jack Daniel was the originator of the square bottle for his whiskey and always wanted to have a matching square glass. Well, here it is! This hefty square glass (each weighs 14 ounces) is the perfect companion to a bottle of Mr. Jack's finest. The inside is rounded to make drinking a pleasure and the original design is fired on for good looks and durability. My **$15.00** price for a set of 4 glasses (8 oz. capacity) includes postage.

**Send check, money order, or use American Express, Visa or Master Charge, including all numbers and signature.**

(Tennessee residents add 6% sales tax.) For a color catalog full of old Tennessee items and Jack Daniel's memorabilia, send $1.00 to above address.

# Skin and Bones

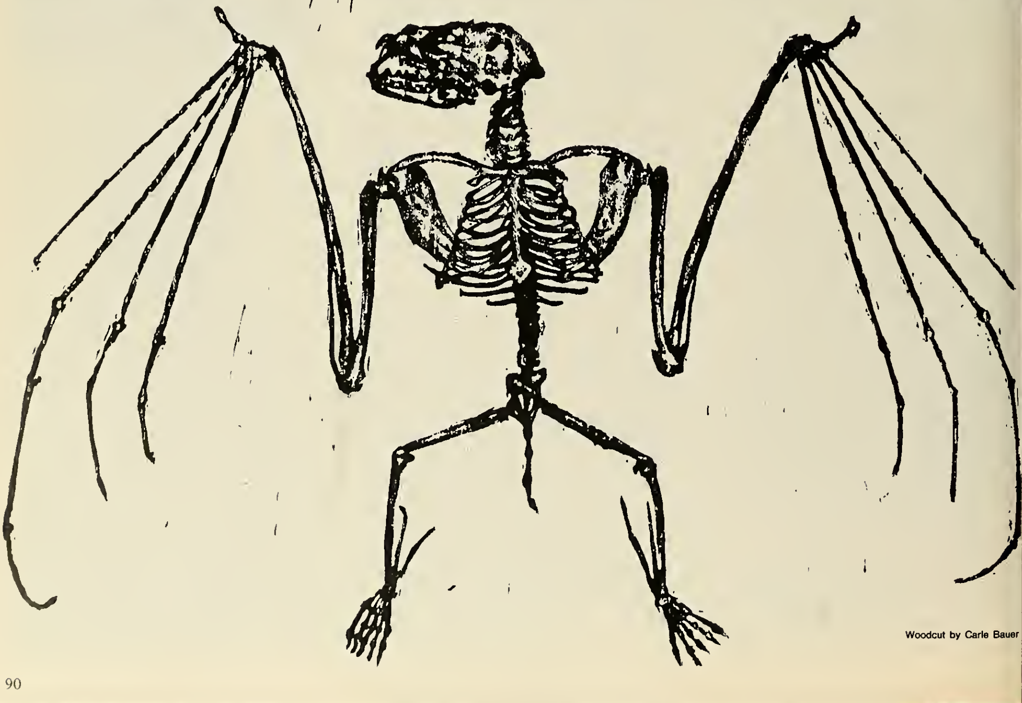
Lying on the floor, arms outstretched, is the frozen body of a female gorilla. Stretched alongside her, also frozen, is a male jaguar. Shelves on the far side of the room hold stacks of skins, including tanned elephant hides from Teddy Roosevelt's collection awaiting the day when they will be used to restore the elephant herd in the Akeley Hall of African Mammals. Assorted animal remains and skinned carcasses in plastic bags are scattered about the room, and in the far corner, two Siberian tigers stare at the scene with fierce but sightless eyes.

The mammalogy freezer is often the first stop a dead animal makes upon arrival at the American Museum of Natural History. Most animals are collected by curators and other scientists on field expeditions, but the Museum also receives animals that have died in zoos. The female gorilla, for example, died at the Bronx Zoo, and after an autopsy, she was given to the Museum.

Dead animals are useful to the Museum in several ways. Field specimens are used primarily for research (although some find their way to exhibition halls) and are valuable for a wide range of scientific studies in evolution, phylogeny, and taxonomy. Zoo animals may be used for research or teaching.

The problem Museum technicians face is how to reduce an animal—which may weigh up to 1,500 pounds—to skin and bones. The process, while fascinating, is not without its unpleasant aspects.

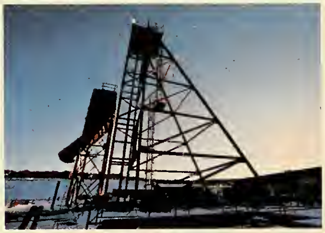
Bill Coull is the senior technician in charge of preparing animal skins. The tannery where Coull works is across the hall from the freezer; among other



Woodcut by Carle Bauer

**We got this oil by cooking rocks."**

"Cooking isn't exactly the right word," says Gulf engineer John Selters. "Actually we heat the rock – oil shale – to about 900°F. The heat releases a kind of oil called kerogen. The idea is to refine the kerogen and use it instead of petroleum.



*"The oil shale is mined 800 feet down."*

"There are huge oil shale deposits in America. According to some calculations, these deposits contain as much oil as there is in the Middle East.

"Gulf and another oil company are equal partners in a project in Rio Blanco County, Colorado, to make shale oil a practical alternative to expensive imported crude oil.

"It's a costly proposition. We're still at the development stage and production is years away. But we'll need the oil then even more than we do now.

"Of course Gulf is still working hard to find and produce all the domestic petroleum and natural gas we can. But we're also working hard on alternatives. Oil shale is just one of many. It takes energy to produce energy, and at Gulf we're giving it our best shot."

tanning equipment it contains vats, beaming boards, and sawdust tumblers. The skull of a pigmy right whale, which Coull is repairing, dominates the center of the room, and trophy heads donated by generations of sportsmen hang on the walls. The tannery adjoins a large room where mounted specimens from former exhibits are stored.

The first step in preparing a hide Coull explains, is to remove it from th animal. When a large animal, such a the gorilla, is frozen, it will take several days to thaw out, so Coull ofte paints parts of the skin wit formaldehyde to retard spoilage. Afte skinning the animal, Coull throws th skin over a beaming board and removes excess fat and flesh with

River Safari in Borneo

with visits to wildlife reserves and archaeological sites in Java and Bali

SEPTEMBER 7 TO OCTOBER 1, 1980

Nine days are spent touring West and Central Java, including a three-day visit to the splendid Ujung Kulon Nature Reserve, followed by a train journey to the Borobudur, the world's greatest religious monument, which we see at sunrise.

We then fly to Borneo, to cruise for one week on the Mahakam river and its tributaries, striking deep into the Dayak country with its remarkable wildlife, where we attend village ceremonies and sleep one night in a native longhouse. The tour ends with two days of well-earned comforts on the island of Bali, and is escorted by an accomplished leader.

beaming knife, a technique thousands of years old. When the skin is reasonably clean, Coull shaves it to a uniform thickness with an electric shaving knife, removes cartilage from the ears and nose, and splits the double layer of skin around the lips and eyes.

The skin is now ready to be tanned. Coull soaks it for ten days in a solution of salt, alum, and soda ash to preserve it and render it pliable. In the final stage of skin preparation, he rubs neat's-foot oil into the hide and allows the oil to soak in. When the skin is dry, he puts it into a sawdust-filled nine-foot drum where it tumbles for about an hour to remove excess oil.

The carcass is another story. It may either be reduced to bones immediately or refrozen for future preparation. Steve Medina is the senior technician in charge of osteological preparation. "There are," he says, "two primary methods of preparing a carcass—bacterial maceration and the bugs." Maceration is used for large animals whose skeletons do not need to remain articulated, while the "bugs" (dermestid beetles) work best for smaller animals and for portions of bigger animals when curators want the complex skeletal parts to remain articulated. Maceration takes place in the osteology preparation area, a large, sunny room that looks out over Columbus Avenue. Along one wall are six tanks: three small, stainless steel sinks, two converted bathtubs, and one enormous vat used for macerating larger animals, such as whales and elephants, and for bleaching bones that will be used for exhibition.

The first step in bacterial maceration is to "rough out" the carcass by eviscerating it and trimming off excess muscle and tissue. "You don't want to take off too much," says Medina, "otherwise it will take longer to macerate thoroughly." The roughed-out carcass is placed in a tank of lukewarm tapwater, where it remains for perhaps a week. During that time, bacterial action digests and dissolves muscle, fat, and other tissues, which float to the surface as a scum that is easily drained off, leaving the bones behind. The bones are finally boiled in a solution of cleaning soda, and any remaining bits of tissue are removed by hand. Maceration, as you can imagine, generates quantities of unpleasant gas. Although large vents above the tanks draw off most of the rising vapors, Medina says that "it can get pretty bad in here."

# Books

from The American Museum
of Natural History

COSTUMES OF THE EAST, by Walter A. Fairservis, Jr., shows the great variety of exotic, romantic garments worn by the peoples of Asia, from the Middle East to China, from Lapland to Japan. Cultural and geographic aspects of the clothing are discussed, and beautiful color plates and black and white drawings show the rich detail of the costumes. Anthropologists, clothes designers, and devotees of Oriental art will appreciate the value of this book both as a reference and for sheer pleasure. Cloth $15.00, paper $5.95

ANCIENT MEXICO AND CENTRAL AMERICA, by Gordon F. Ekholm, analyzes the art and architecture of precolumbian Middle America. Superb color and black and white photographs by Lee Boltin picture items from the Museum's Hall of Mexico and Central America. Archeologists and sculptors will find this book beautiful as well as informative. Paper $5.00

BUTTERFLIES OF THE AMERICAN TROPICS, by William Phillips Comstock, is the definitive work on the genus *Anaea*. With 30 full-size color plates and hundreds of detailed drawings, this authoritative publication is a must for collectors of extraordinary books as well as for collectors of Lepidoptera. Cloth $25.00

CURASSOWS AND RELATED BIRDS, by Jean Delacour and Dean Amadon, explains and illustrates the habits and biology of curassows, guans, and chachalacas, a fascinating group of gamebirds from tropical America. This large volume has 30 magnificent color plates of paintings by Albert Earl Gilbert, George Miksch Sutton, and David Reid-Henry, as well as many drawings, photographs, and maps. Ornithologists and lovers of fine bird paintings will delight in this work based on several field trips and extensive research. Cloth $20.00

NATURALIST'S COLOR GUIDE, by Frank B. Smithe, is important to all naturalists, especially ornithologists, whether amateur or professional. Part I, a pocket-size binder with 86 swatches of named, measured colors, is essential for precise identification and description of birds and other animals. Part II, a paperbound supplement, discusses each color, how it was named and measured, and the work of various color specialists, such as Robert Ridgway. Part I $9.00, Part II $5.00, both parts together $12.00. Part III available soon.

the famed dermestid beetles are the preferred method. These small, voracious beetles eat the flesh of an animal, leaving behind a spick-and-span, articulated skeleton. The dermestids have attracted much attention from the press and have been featured in the *New York Times* and the *Washington Post*. Visitors to the dermestid room—a dark, humid chamber in which the beetles thrive—must negotiate an assortment of specimens in alcohol, mounted specimens, and an ancient plaster cast of an elephant ear.

The beetles' current assignment is some fifty dried bats, a monkey, a fox, and an iguana. Given the right conditions, the dermestids take about a week to polish off an animal, at which time they are lured off the bones by a new feast. The clean skeletons are then

**Peruvian Weaving**

For forty-five centuries the weavers of Peru created intricate and sophisticated textiles. For the May members' program, Wednesday, May 14, at 7:30 P.M., in the Auditorium, Junius Bird and John Cohen will use contemporary and archeological evidence to discuss the weavings of Peru and will première Cohen's new film *The Weavers of Peru*. Members are admitted free, nonmembers may purchase tickets for $3.00 at the door.

**Glass Menagerie**

A menagerie of insects and other arthropods will be displayed in the Education Hall on Sunday, May 11, from 11:30 A.M. to 2:30 P.M. *Insect Day*, the May family membership program, will feature live tarantulas, black widow spiders, centipedes, scorpions, and cockroaches—all safely ensconced behind glass. Museum curators will also be exhibiting some of their favorite mounted specimens from the collection. *Insect Day* is open only to members of the Museum and their guests.

**The Past Researched**

The New York Society of the Archeological Institute of America and the Museum's Department of Education are presenting *Visions of Antiquity*, a film series that deals with different aspects of several archeological excavations. Excavations in Egypt, on the island of Thera (Santorini), and of a sunken Greek ship will be the focus of three Monday evenings, beginning May 5. Filmmakers laced in a sealed cabinet with moth-alls to kill any stray beetles, which ould otherwise continue to gorge hemselves on specimens in the collec-ions. A final immersion in a solution f ammonia removes any remaining rease, odor, and bits of tissue from he bones; after this, they are dried, la-eled, and matched with their skins nd other parts before being installed n the research collections.

Such specimens are now ready to be tudied by Museum curators, outside cientists, and graduate students. Last ear, the Museum's Department of Mammalogy made more than 300 oans, involving 4,000 specimens (most repared with the above methods), to cientists and institutions around the world.

*Douglas J. Preston*

and archeologists will lead informal discussions after two programs. For tickets, write the Department of Education at the Museum.

**Insect and Spider Films**

The Museum's Department of Education is offering a free weekend film festival, *Insects and Spiders*, on May 10 and 11 from 2:00 to 4:30 P.M. in the Auditorium. The films explore the lives and habits of butterflies, bees, spiders, ants, termites, and other small creatures.

**Feather Arts**

A new exhibition at the Museum explores the use of feathers in art, religion, and decoration. *Feather Arts: Beauty, Wealth, and Spirit from Five Continents* covers 1,000 years of history, features 250 artifacts made of feathers, and is illustrated with historical photographs, engravings, and brilliant mounted bird specimens. Some highlights of the exhibition are an effigy of the Hawaiian war god Kukailimoku, collected by Capt. James Cook; feather baskets made by the Pomo Indians of California; and a White Mountain Apache war headdress.

**New Guinea Headdresses**

A companion exhibit to *Feather Arts* explores the complexity and variety of headdresses from New Guinea and includes photographs of the birds of paradise used to create them. *Papua New Guinea: A Feather in the Cap* will remain on display in the Akeley Gallery until September 1.

Colleen McCullough,
author of
THE THORN BIRDS
AUSTRALIA

"If you're up for adventure, come on Down Under."

"Join a rugged safari tour where the paved road ends. Begin a journey you can only make in Australia. Experience spectaculars like my own beautiful 'Thorn Birds' country—the awesome Outback. The Great Barrier Reef. Living deserts and tropical rain forests.

"Our adventures are as varied as the land. See kangaroos, cockatoos, emus and koalas. Go game-fishing, mountain-climbing, bush-walking, camel-trekking. Ride a sheep station. Skipper a yacht. Or pan for gold.

"With lower-than-ever airfares, Australia welcomes you with good, down-to-earth values. Come on Down Under—it's even better than the book."

# In Search of a Proper Tillamook

*The demand for Oregon's own cheddar cheese leaves little time for aging*

**by Raymond Sokolov**

First there were the mountains of the Coast Ranges and, in between them, lush green meadows. The climate was mild and grass grew thick all year. This dairyman's utopia was what Joe Champion saw when he landed by whale boat in Tillamook Bay one April morning in 1851. Champion had sailed down the Oregon coast from Astoria at the mouth of the Columbia River to settle this remote but lovely corner of the earth.

"The Indians," wrote Champion, "generally seemed pleased with the prospect of having the whites to settle among them [poor fools].

"They showed me a large hollow Spruce Tree into which we conveyed all my property."

He lived in the tree for a month and then built a cabin. That same year, other rugged pioneers followed Champion to Tillamook, driving herds of cattle that waxed fat on the pristine pasture and gave milk in wonderful abundance. But there was no practical way to ship the milk out of Tillamook. The only land route over the summit of the Coast Ranges was an Indian track. The county did not get a rail connection with the outside world until 1911. Boats were undependable and slow. Milk was bulky and perishable.

Cheese was the answer. It was compact and kept extremely well. So the Tillamook pioneers made cheese from their milk and in 1855 built a ship called the *Morning Star* to carry it up the Columbia River to market.

Little cheese factories sprang up everywhere, amateur operations that resulted in a bewildering array of cheeses—some good, some bad. Eventually, in 1894, an itinerant cheesemaker from Ontario, Peter McIntosh, introduced the standard cheddar process he had learned back east.

By 1894, cheddar was already an established part of life in many parts of North America. The first cheddar factory in the United States had been set up in 1851 by Jesse Williams near Rome, New York. This hard, bacterially cultured whole-milk pressed cheese was British in origin, where it was invented some time before 1664, in the Somersetshire village of Cheddar, near Bristol. Yet it assimilated itself in the New World so well that it was often known as American cheese. New Englanders spoke of it familiarly as rat cheese or store cheese.

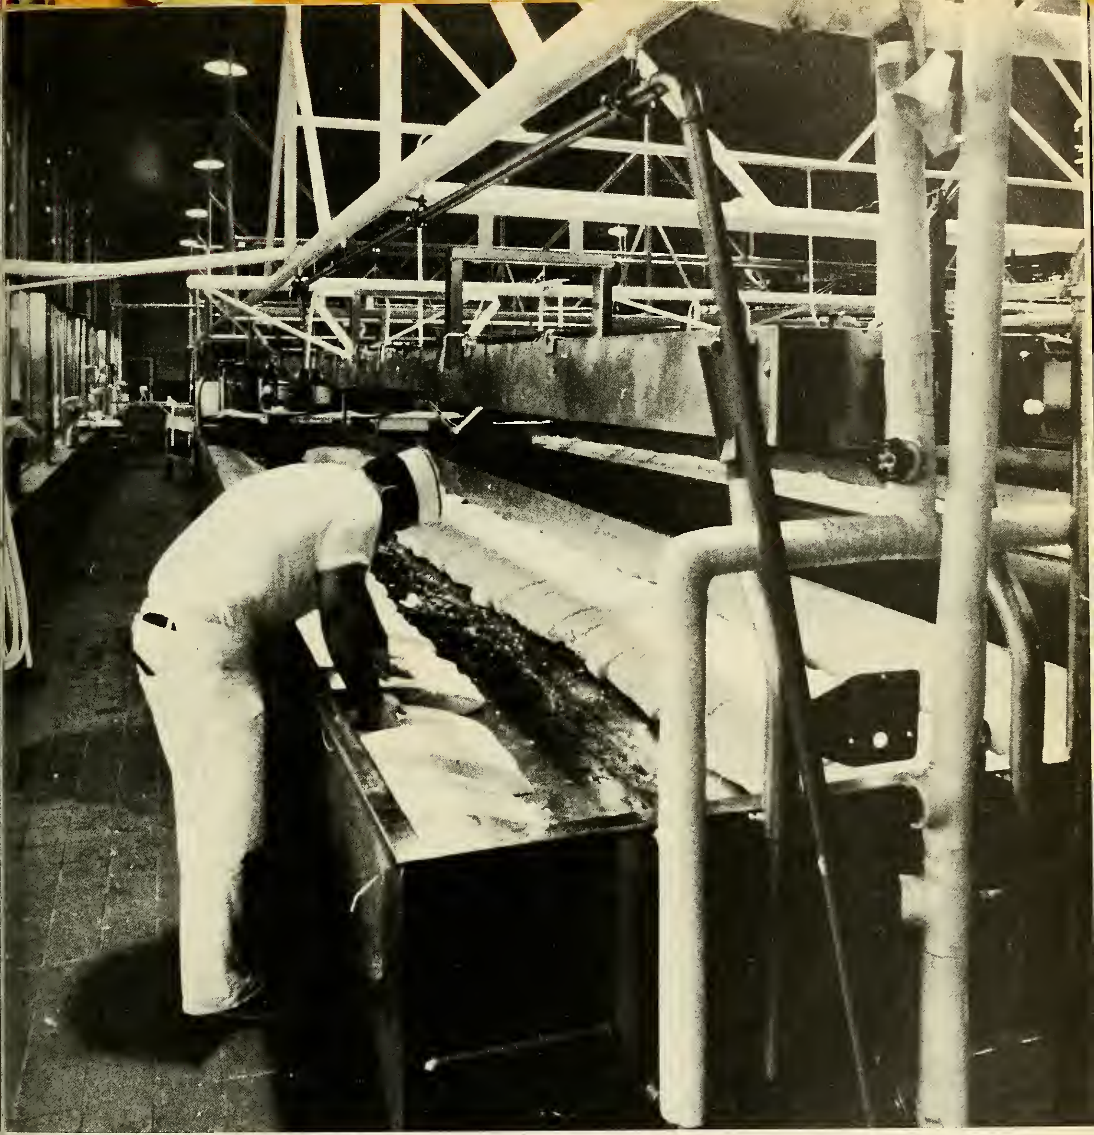
Tillamook cheddar ought to have been just another example of the same ubiquitous product. But those sturdy Pacific Northwest yeomen who made it aged their cheddar longer than the standard six or seven months. They liked their cheese as sharp and mature as possible. Two whole years of curing was not unusual.

Something else crucial separated the Tillamook cheesemakers from their competitors in other places, even from those in other locations along the Oregon coast. The Tillamook factories had a flair for modern marketing. As early as 1909, they banded together as the Tillamook County Creamery Association, standardized their production, and adopted Tillamook as an exclusive trade name.

Today, you can learn all about the progressive consolidation of the Tillamook factories in the museum at the giant plant on Highway 101 just north of the town of Tillamook. Out in front is a full-scale replica of the *Morning Star*, which is the Tillamook logo.

The plant itself is now the only factory producing cheese for the Tillamook label. It is a model of spotless, automated mass production and worlds apart from the cheesemaking of olden days commemorated in the exhibit of antique cheese vats and tools in the plant museum or from the battered fifty-gallon copper cheese kettle in the Pioneer Museum in town.

In the visitors' observation area of the plant, you can watch the cheesemaking process through a glass wall. Oregon's strict health laws forbid visitors going out on the plant floor, but the overhead view of the five 15,500-quart vats is dramatic all the same. A sea of milk cultured with lactobacilli and rennet curdles while automatic stirring devices sweep slowly through the vats. Whey gradually drains out of the vats, leaving behind curds that remind you of scrambled eggs. Then a man appears. He cuts a lengthwise ditch down the middle of the vat, leaving the curd packed together on either side. In a few minutes, the curd is firm enough to be turned without breaking and it is time for him to "cheddar" the cheese. He cuts the curd into slabs several inches wide. He works with machinelike precision, cutting dozens o identical loaves of curd, then turning them so that whey runs out uniformly and rapidly. The firm slabs then trave on a conveyor belt to a milling machine that cuts them into fingerlike pieces, washes them, adds a smal amount of salt, and packs them in hoops.



*Cheese kitchens, Tillamook Cheese Factory*

Scott Blackman

Each hoop holds forty pounds of curd, which is pressed for three hours. The pressed blocks go into a curing area with a ten-million-pound capacity, where the temperature is always 38 degrees Fahrenheit. Federal law requires that cheddar be cured for sixty days. Medium Tillamook is, in fact, cured for three months. The sharp cheddar ages for seven months.

On my way out of the observation area, I walked through the factory gift shop and bought some sharp cheese. In the parking lot, I cut into the package, feeling in direct contact with Tillamook pioneer days as the annatto-colored cheese emerged. The Coast Ranges loomed on the horizon. *Morning Star II* was only a few feet away. I tasted the cheese.

It was mediocre. Not bad. Clearly a cheddar, with a respectable tang to it, but not the stellar cheese I had once tasted in the home of a New York epicure whose Oregonian wife had imported it from a special source in her home state.

But I had been warned. James Beard, himself an Oregonian, had told me I would probably not find old-fashioned, aged Tillamook cheese in Oregon. The demand is too great these days. The cost of holding the cheese in the curing room for two years is prohibitive. M. Wayne Jensen, Jr., director of the Pioneer Museum and the son of a cheesemaker, told me much the same thing. He remembered when farmers used to leave cheeses in the factory curing area to age like cigars in the Dunhill humidor room. He even remembered tasting a cheddar that had been cured right through World War II. "It was a bit crumbly," he conceded, "but good, good and sharp." Nevertheless, he didn't know where I would find even a two-year-old cheese today.

James Beard had suggested that I might ask around at the factory. Some of the employees might be aging cheese at home. I left my car and accosted the first worker I saw. "Yes," she said, "I've got some in my refrigerator right now. I keep it sealed in the back of the vegetable drawer for two years. Just turn it once a week."

If I wanted to buy some old cheddar, she said, I might try at the market up the coast in Bay City.

The C & W Markette is a little country store in a very small town. You would not ordinarily stop there on your way north along the gorgeous coastal highway. And even if you did, you would probably notice nothing special about the place except for the homemade beef jerky in the meat department. But the well-informed turophile at the C & W walks briskly to the back of the store and snaps up some peculiar little packages of cheddar in plastic bags. They sell for more than the brand-name cheddar in the same display area, but the price is not at all outlandish: $3.45 per pound. They look just like other cheddars, but they are sublime. Not aggressively sharp, yet undeniably vigorous, these special cheeses are luxuriously dense but not at all crumbly. They are, indeed, curiously smooth, with a complexity of taste that would make Peter McIntosh proud.

"I buy medium cheddar from the factory by the ton," says Frank Walz, proprietor of the C & W. "Then I age it at 32 degrees for three years. It's easier that way. It would go faster at 55, but I'd have to turn it all the time."

Tradition dies hard in Oregon. The Tillamook central plant keeps the legend of its cheese alive, and it manufactures the raw material for traditional aged cheese. Frank Walz, who migrated west from Minneapolis twenty years ago, does the rest. And in my New York refrigerator, five pounds of factory-sealed cheese sits quietly in the back of the vegetable drawer. I turn it from time to time, thinking of pacific cows, thick grass, and Joe Champion in his hollow spruce.

### Oregon Fish and Cheese Casserole

(Adapted from Carol Cate's *Clam Dishes and Rock Fishes*, available from Carol's Cookbooks, P.O. Box 795, Winchester, Oregon 97495)

1½ pounds rockfish (fleshy white fish) fillets
1 teaspoon salt
¼ teaspoon pepper
1 cup whole-kernel corn
1½ cups green beans, cooked
2 cups cooked potatoes, sliced
¼ cup butter or margarine
2 tablespoons lemon juice
2 tablespoons grated onion
1 tablespoon chopped parsley
2 medium tomatoes, peeled and sliced
¼ cup grated cheddar cheese (1 ounce)

1. Cut fish into 3 or 4 serving-size portions and sprinkle with half the salt and pepper. Preheat oven to 350 degrees.
2. In a large, well-greased casserole, place in layers the corn, green beans, and potatoes, sprinkling each layer with the remaining salt and pepper.
3. Combine butter or margarine, lemon juice, onion, and parsley. Dip fish into mixture and arrange on top of potatoes. Cover with tomato slices and cheese.
4. Bake 1 hour and 15 minutes or until fish flakes.

Yield: Three to four servings

### Welsh Rarebit

(From Bert Greene's *Kitchen Bouquets*, Contemporary Books)

2 tablespoons unsalted butter
3 egg yolks
1 teaspoon Dijon mustard
½ teaspoon beef bouillon powder
1 teaspoon imported soy sauce
Dash of hot pepper sauce
Pinch of ground allspice
¾ cup light beer
10 ounces sharp cheddar, grated
1 tablespoon heavy cream
1 teaspoon Scotch whiskey
4 slices hot buttered toast

1. Melt butter in a double boiler.
2. Beat the egg yolks with the Dijon mustard, bouillon powder, soy sauce, hot pepper sauce, and allspice. Stir in the beer.
3. Add the beer mixture to the melted butter; place over simmering water. Stir until hot. Add the grated cheese, ¼ cup at a time, stirring constantly in one direction with a wooden spoon until mixture is smooth.
4. Stir in the cream and Scotch. Do not let mixture stand more than 5 minutes before serving over hot, buttered toast.

Yield: Four servings

If you have ever taken a luxury sports car through a tight turn, you know the feeling. It's the sense of supreme precision with which this trim, compact camera proclaims its Nikon heritage. A feeling that is borne out by the professional quality pictures the Nikon FE delivers with automatic ease. And one that, unlike other fine things in life, is readily affordable.

*With the Nikon FE,* you can simply focus and shoot... and rely on its Nikon electronics to give you sharp, magnificently exposed photographs, automatically. Or, switch to manual operation and enjoy complete creative control over every exposure, more easily than you ever thought possible.

*Above all,* this is a camera that makes no compromise in its supreme Nikon quality. Stroke the advance lever, and feel the smoothness of precision gearing machined to microscopic tolerances. Press the exposure button, and hear the shutter respond with hushed precision. Look through the bright, silver-coated viewfinder, and see your picture snap into sharp focus with a fingertip touch.

*Know, too,* that the world's greatest photographic system stands behind your Nikon FE. Add the dynamic firepower of motor drive, at up to 3.5 shots a second. Banish darkness with the ingenious automatic thyristor flash. Explore new perspectives through more than 60 Nikkor lenses, the same superb optics chosen by most professionals for their sharpness and color fidelity.

**For the purist:**

**The Nikon FM**

For those who prefer only manual exposure control, the Nikon FM offers the reliable guidance of one-step electronic metering. It's as compact and precisely responsive as the FE and costs even less. At your Nikon dealer.

# MEETING THE DEMANDS OF SOCIETY IS NO EXCUSE FOR BUILDING A BORING CAR.

If one accepts the dismal prophecies emanating from the automotive community, it appears we are destined to suffer a generation of thoroughly boring automobiles.

Cars so utterly debilitated by societal necessities, safety regulations and antipollution paraphernalia that they no longer will be the least bit interesting to drive.

All this pessimistic doomsaying, however, neglects to take into account the obsessive determination of the engineers at BMW in Munich, Germany to build extraordinary automobiles.

Against all odds, the BMW 528i not only satisfies the laws of the land and the demands of the gas tank, it does so without ever once violating our conviction that extraordinary performance is the one rational justification for owning an expensive car.

## FEW CARS PERFORMED THIS WELL BEFORE POLLUTION CONTROLS.

"Expensive sedans," writes Car and Driver magazine, "tend to ride like pillows when you cruise them and squeal like pigs when you push them."

A bit caustic perhaps.

But, an analysis that makes the performance statistics of the BMW 528i seem all the more remarkable.

Round a particularly hair-raising curve and the legendary BMW suspension system—independent on all four wheels—flexes with a resiliency that makes one feel as if the car were built into the roadway.

Press the accelerator and the 528i's fuel-injected, 2.8-liter, overhead cam engine responds in a manner that can only be described as exhilarating—even by pre-pollution control standards.

Yet, the BMW 528i (with 5-speed standard transmission) delivers $\boxed{18}$ EPA estimated mpg, 30 estimated highway mileage and, based on these figures, an mpg range of $\boxed{295}$ miles and a highway range of 492 miles.

(Naturally, our fuel efficiency figures are for comparison purposes only. Your actual mileage and range may vary, depending on speed, weather and trip length. Your actual highway mileage and highway range will most likely be lower.)

## LUXURY NEEDN'T BE MERELY A FACADE.

One's taste for luxury would have to be insatiable indeed to imagine an appointment or convenience lacking in the 528i.

AM/FM stereo cassette, full-power accessories, air conditioning, and the like, are all standard equipment.

Yet each and every facet has been strategically engineered to help eliminate the enormous strains of driving.

Its seats are anatomically shaped buckets. Its front seats are so thoroughly adjustable that it is all but impossible not to find a comfortable driving position.

All in all, in a time of lowered automotive expectations, amidst increasing mediocrity, the engineers at BMW have actually improved the BMW 528i.

If you find the notion of owning such a car more than a little intriguing, we suggest you phone your nearest BMW dealer and he will arrange a thorough test drive for you.

Soon after arriving as a student at Florida Southern University from his native Baltimore, **David S. Lee** noticed the conspicuous mounds of pocket gophers dotting the landscape. Six years ago, having taken a position with the Florida State Museum, he began to study the elusive, subterranean rodents that were responsible for the mounds. At present, Lee is curator of birds and mammals at the North Carolina Museum of Natural History and goes afield every year to observe more of the life style of the pocket gopher. He is also involved in an extensive study of the sea birds of North Carolina's offshore waters. A writer and photographer as well as a biologist, Lee has developed an avocational interest in native orchids and ferns.

As a boy in Maine, **Bernd Heinrich** was already involved with caterpillars; he hunted them to raise into moths and butterflies. His subsequent Ph.D. work at the University of California at Los Angeles began as a project on the feeding behavior of sphinx moth caterpillars, but ended as a study of temperature regulation in the moths themselves. A professor of entomology at the University of California at Berkeley, Heinrich now concentrates his research on the physiology and behavior of foraging insects, a subject he covered in his recent book, *Bumblebee Economics* (Harvard University Press, 1979). He is also a marathon runner and last February, at age 39, set his best time for the 26-mile, 385-yard course—2 hours 22 minutes. (The Olympic record is 2 hours 9 minutes 55 seconds.)

Cloud physics is **John Hallett**'s particular interest, in pursuit of which he flies through storms in research aircraft and conducts laboratory and field studies on growth processes of hailstones and snow crystals. Born and educated in England, Hallett has lived in the United States for two decades. He is research professor of atmospheric physics at the Desert Research Institute of the University of Nevada and concurrently teaches graduate and undergraduate courses in atmospheric and environmental science.

**Reid A. Bryson** is a professor of meteorology and geography at the University of Wisconsin, Madison, and since 1970 has been director of the university's Institute for Environmental Studies. In line with his interdisciplinary approach to subjects under investigation, he has applied climatic information to cultural changes among North American Plains peoples. Bryson has been on archeological digs in Canada and the United States, has studied climatic modification in India, and has written widely on climatic subjects for scientific journals and the popular press. Future research projects include an effort to develop a unified theory of climatic changes.

**Dmitri Ivanovich Bibikov** is a senior researcher with the Institute of Evolutionary Animal Morphology and Ecology of the USSR Academy of Sciences in Moscow. His current research into the ecology of carnivores and rodents also embraces the field of medical zoology. In 1972, while attending the General Assembly of the International Union for the Conservation of Nature in Banff, Canada, he participated in that organization's Wolf Working Group. That triggered his interest in wolves, one that he is still pursuing, along with his earlier studies of marmots. Bibikov has done fieldwork in central Russia, the Caucasus, the Trans-Baikal region, the Far East, the mountains of Central Asia, and the deserts of Kazakhstan. He lists his hobbies as hunting and fishing.

## Bells Toll Warning to Whales

"When we wrote that article, the fishermen saw no way out except killing whales," Jon Lien recalls of the situation in Newfoundland last spring. As he and Bora Merdsoy reported in "The Humpback Is Not Over the Hump" (June/July 1979), whales chasing capelin, a small fish that codfish also feed on, were becoming entangled in cod traps, wreaking economic havoc on the fishermen.

Now things have improved somewhat. When they wrote the article, Lien and Merdsoy had just developed a means to extricate whales from traps, and they have since refined it. More important, they came up with a workable and inexpensive device to warn whales off cod traps, which are set just under the surface. By attaching an underwater bell, which costs about $2.50, to the traps, they were able to drastically reduce whale entanglements. In tests, 89 percent of the traps without bells were hit by whales while only 30 percent of the traps with bells suffered whale damage.

Lien and Merdsoy are still experimenting with warning devices for gill nets, which are set so deep that the bells will not work, but not so deep that the nets do not suffer whale damage. Nonetheless, the fishermen are not as frantic as they were. At least, says Lien, there were no petitions in Newfoundland last year to lift Canada's ban on whaling.

Whale Research Group

*A team from the Memorial University of Newfoundland extricates a dead humpback whale from a cod trap.*

## The Origin of "Winter Sleep"

When Henry Van Twyver and Truett Allison wrote "The Evolution of Sleep" (February 1970), they speculated that among the blessings of slumber for mammals was energy conservation. Since they need to maintain a constant body temperature, warm-blooded animals have high energy demands, and Van Twyver and Allison proposed that sleep could have evolved as a way for such animals to "turn down the body's 'thermostat' and conserve energy."

Apparently, they were on the right track. Recent work with small mammals by Craig Heller of Stanford University and Ralph Berger of the University of California at Santa Cruz

# HOW GM "PROJECT CENTERS" CREATE CARS

## FROM CONCEPT TO CUSTOMER IN THREE YEARS AND THREE BILLION DOLLARS

Throughout the history of the automobile industry, product change was almost always evolutionary. But in 1973, GM determined that the times required revolutionary changes. It started its first Project Center—which by itself heralded a revolution in the use of science and technology to meet the changing demands of the marketplace. A few months later, the Arab countries launched the oil embargo. Fortunately, machinery was already in motion in GM to create and develop new cars and components in a new way and faster than ever before.

**GM's first Project Center brought out totally new full-size cars:** smaller, yet roomier, and far more efficient than their predecessors. The advertisements said they were "designed and engineered for a changing world"—and they were. Another Project Center, begun in 1975, developed the immensely popular GM X-cars.

Led by the five car divisions, Project Centers gather people, ideas, and knowledge from all 30 divisions and staffs of General Motors. In the first stage, which we call "concepting," experimental engineers, environmental scientists, forward planners, and marketing experts pool their thinking. Their objective: what the marketplace will require. This is the most important stage. Here we must determine not only what kind of car, but how many we might be able to build and sell years later. Economics, customer tastes, availability of various kinds of fuels must be compared with state-of-the-art technology—and what steps must be taken to advance that technology quickly yet surely.

In the "concepting" stage, a new car is conceived. If the car is to be sold to customers three years later, construction of new plants must begin and basic tooling must be ordered.

The second phase of the Project Center takes 24 to 30 months. It encompasses development, design, structural analysis, handling analysis, emissions, noise and vibration, safety, reliability, serviceability and repairability, manufacturing, assembly, marketing, financing.

Advanced product engineers and research scientists work with the one hundred fifty to two hundred people at the Project Center and thousands more in the staffs and divisions to transfer new science and technology to the new car. Components are hand-built and "cobbled" into existing models for road testing.

**Prototype cars are hand-built at a cost of more than $250,000 each.** These enable the Project Center team to determine how newly developed, pretested components operate as a unit. Then, pilot models will be built from production tooling and tested some more. New technology, such as structural analysis by computer, saves time. Lead time has been reduced by 25% from ten years ago, when cars were far less complex.

After almost four million miles, nearly three billion dollars, and nearly three years of work, the new cars—quite unlike anything before them—start coming off the production line at a rate of better than one a minute.

**There are now eight Project Centers in General Motors.** Four are developing new cars using hydrocarbon fuels, one is creating an electric car, and others are working on computerized engines and emission controls, a new kind of automatic transmission, and the inflatable restraint system.

New and revolutionary cars can't be mass produced for the road overnight. But by putting all the parts of General Motors to work together, we found a way to speed up the process. We have integrated the creativity of thousands of human minds to make invention into reality when it's needed.

*This advertisement is part of our continuing effort to give customers useful information about their cars and trucks and the company that builds them.*

Smaller can be better, as the new full-power Nikon Roof Prism Compact Binoculars clearly demonstrate. Pocket-size slim and just 7-1/2 ounces light, they outperform many bigger and heavier binoculars in sharp, bright, distortion-free viewing. You see the entire scene, even while wearing glasses. And, most important, they're so precisely engineered that you can view for extended periods, without strain or discomfort. Available in all-purpose 6x, 7x and 8x models. See the difference Nikon quality makes, at Nikon camera dealers and selected optical departments. Or write to Nikon Inc., Dept. N-26, Garden City, New York 11530. supports the view of sleep as intimately connected with temperature regulation. Heller says their studies suggest that hibernation, which involves greatly lowered body temperatures and has a clear energy-conserving function, is an evolutionary extension of sleep—actually of one kind of sleep called slow-wave sleep.

He also points out that this notion has been anticipated in the common parlance of biologists, who called hibernation "winter sleep," and in the German language, in which the word for hibernation is essentially the same—*Winterschlaf*.

This new view of hibernation is based on several lines of evidence. During both hibernation and slow-wave sleep a part of the brain known as the hypothalamus regulates body temperature. And during both hibernation and slow-wave sleep body temperature drops.

Furthermore, hibernating mammals descend into hibernation through slow-wave sleep. Recordings of electrical impulses from the brain show an increasing predominance of slow waves until an animal reaches 77°F, below which one can't get a good EEG (electroencephalogram). Animals that go into shallow torpor—a state between sleep and hibernation in which body temperature drops a few degrees—show a predominance of slow waves throughout their torpor greater than that during normal sleep.

These similarities in EEG and temperature regulation, says Heller, put sleep, shallow torpor, and hibernation on a continuum, and suggest that hibernation is not an evolutionarily primitive phenomenon but a specialized adaptation that evolved out of slow-wave sleep.

What is not on the continuum is the other kind of sleep—called REM (rapid eye movement), or paradoxical, sleep. During this kind of sleep the eyes move rapidly and the brain exhibits electrical activity that resembles the pattern of wakefulness, while the muscles (paradoxically) lack tone, leaving the body effectively paralyzed. What puts REM sleep off the continuum is that it is also characterized by a lack of thermoregulation. The hypothalamic temperature control present at other times is absent.

Why it is absent is as much of a puzzle as REM sleep itself, for which a physiological explanation, according to Heller, is not yet in sight.

*James Gorman*

# Come backstage with us...

Yes, come backstage. Wander through the music stands. Look in on the performers warming up. The stage manager. The anxious composer.

Keep going. Wander to the performer's studio. Share the final preparations the day before the concert. Be there the month before the concert. The year before.

Go to the rehearsals. The auditions. The lessons. The exercises. The selection of a teacher. The making of a repertory. The promotion. The choosing—and arranging for—the concert hall.

What makes this performance happen? Even more intriguing—**What (besides talent) makes this PERFORMER happen?**

Now you can find out from the artists themselves in—

Virtuoso

The new bi-monthly magazine for concert- and opera-goers, for performing professionals and serious students, for teachers and coaches.

Every issue, you'll explore the "how-to's" of daily musical life—in penetrating articles often written by virtuosi themselves. For example, the premiere issue alone includes these inside stories that you just won't find anywhere else:

- Flutist Paula Robison tells how she prepares and stages her famous concert series ("Paula and..."), now in its 4th season
- An exclusive in-depth article on how the New York Philharmonic auditions to fill a place for one violinist
- Pianists Emanuel Ax and Ann Schein affectionately remember their master teacher Mieczyslaw Munz
- A dynamic picture story on a recording session with English horn player Thomas Stacy
- A special 16-page guide to summer festivals throughout the country: artists, dates, locations, public transportation, driving directions, and a lot more
- How it feels to be a child prodigy grown up—from one who knows

In every issue, you'll learn from accomplished artists how they develop the techniques that define virtuosity. How to design exercises for a particular repertory. How different artists prepare for their concerts.

Successful teaching techniques—as seen by both the master teachers and their virtuoso students. How composers **make** opportunities for having their work performed. What goes into selecting a recital hall. How to produce a recording. The special challenges of editing and performing early music.

There will be regular features about new books, recordings and performances throughout the country, as well as...

Visits to concert halls in major cities—and reports on their sound quality, audience comfort, frequency and types of concerts, and more.

Reviews of **reviewers.**

Now you can subscribe to Virtuoso at the special charter member rate of only $9.97/year (6 issues). **That's a saving of over 15% off the regular subscription rate!**

**There's no risk.** Fill out and mail the coupon and we'll rush you your first issue by return mail. We'll bill you later. If you choose to cancel your subscription, simply write "cancel" on the bill and return it to us.

**So to start "coming backstage with us" right away—and to take advantage of our special Charter Subscription offer—subscribe now.**

# “Everyone Here Spoke Sign Language”

*For many generations on Martha’s Vineyard, deafness was no bar to a full social life*

**by Nora Groce**

The fifth of April, 1715, had not been a good day for Judge Samuel Sewell of Boston. On his way to the island of Martha’s Vineyard there had been trouble finding a boat to cross Nantucket Sound. The vessel then lay for hours without wind, and once it was across, the horses had to be pushed overboard to swim for shore on their own. Sewell and his company reached shore at dusk—cold, hungry, and in bad humor. Finding a group of local fishermen nearby, the judge engaged one of them to guide him to Edgartown and later noted in his diary: “We were ready to be offended that an Englishman . . . in the company spake not a word to us. But,” he continued by way of explanation, “it seems he is deaf and dumb.”

This Englishman was indeed deaf, as were two of his seven children. His is the first recorded case of what we now know to be a form of inherited deafness that was to appear consistently within this island population for more than 250 years and affect dozens of individuals. Probably one or several of the small number of settlers who originally populated the area brought with them a trait for hereditary deafness. As long as the “gene pool” remained limited in the small island population, this trait appeared with high frequency in subsequent generations. Put another way, the founders of this isolated society had a greater likelihood of perpetuating the trait for congenital deafness than if they had been part of a larger, changing population.

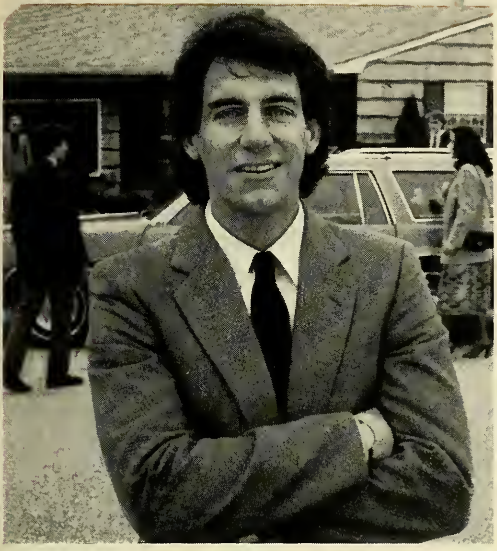
Martha’s Vineyard offers what I feel to be a good example of the way in which a community adapts to a hereditary disorder. Lying some five miles off the southeastern coast of Massachusetts, the island was first settled by Europeans in the early 1640s. The population, of predominantly English stock with some admixture of indigenous Wampanoag Indian, expanded rapidly, owing to a tremendously high birthrate. Families that had fifteen to twenty children were not uncommon and twenty-five to thirty not unheard of. Although several hundred households are listed in the census records of the mid-eighteenth century, only about thirty surnames are to be found, and during the next century and a half only a handful more were added to the original group of names.

After the first generation, marriage “off-island” was rare. While Vineyard men sailed around the world on whaleships, merchantmen, and fishing vessels, they almost invariably returned home to marry local girls and settle

POST OFFICE

*This post office-general store was often the scene of sign-language conversations.*

Courtesy of Stanton Lair, Martha’s Vineyar



# One of these men drives himself to work, drives himself home and drives up his cost of living.

He doesn't see it that way. He's been driving himself to the office every day for several years now. He actually enjoys the ride.

Problem is, with today's energy crisis, the man on the right is wasting both fuel and money. Gas prices alone make the trip expensive. And his auto insurance premium is higher than it has to be.

The man on the left has decided to conserve and save. When the gasoline shortage began, he and some neighbors started carpooling to work. So together they consume less gas. That cuts expenses right there. What's more, because each of them drives fewer miles, they save money on their auto insurance as well.

As a major group of property and casualty insurance companies, we're doing our best to help you keep your insurance rates affordable. That's why most auto insurers are offering discounts to those individuals who reduce the total number of miles or times they drive to work.

For example, people who normally drive 30 miles to and from work every day can save up to 22% on car insurance premiums just by carpooling. All they have to do is drive to work two days a week instead of five.

People who switch to public transportation to get to work save even more on their premiums—up to 31% in some states. Their car becomes classified "for pleasure use only," a less expensive category.

**Here's what we're doing to control costs:**

- Offering premium discounts to those who reduce the total number of miles they drive each week to work. Discounts will vary by company, by state and by the type of coverage you have.
- Cracking down on insurance fraud practices through the Insurance Crime Prevention Institute and the National Automobile Theft Bureau.
- Working through the Insurance Institute for Highway Safety to make cars and roads safer.
- Investigating injury and repair claims more thoroughly.

**Here's what you can do:**

- Cut down on your driving by carpooling or by using public transportation.
- Use your auto seat belt and shoulder harness.
- Talk to your insurance agent or company about ways to lower the cost of your auto insurance coverage.
- Lock your car. Don't invite trouble.

## Affordable insurance is our business...and yours.

down. Women married off-island even less frequently than did the men. Contact with the mainland was said to be more sporadic than with foreign countries. In the nineteenth century, islanders claimed that more of their men had been to China than to Boston, only eighty miles away. Even today, many islanders have never been to the island of Nantucket, barely eight miles to the east.

Throughout the seventeenth, eighteenth, and nineteenth centuries, marriage patterns on the island followed the customs of any small New England community. Most of the islanders, however, could trace their descent to the same small nucleus of original settlers, indicating that although they were unaware of it, considerable "inbreeding" took place. The result was that during these two and a half centuries, within a population averaging little more than 3,100 individuals, hereditary deafness occurred at a rate many times that of the national population. For example, in the latter part of the nineteenth century, an estimated one out of every 2,730 Americans was born deaf. On Martha's Vineyard the rate was closer to one out of every 155. But even this figure does not accurately represent the distribution of deafness on the Vineyard.

Marriages were usually contracted between members of the same village, creating smaller groups *within* the island's population characterized by a higher frequency of deafness. The greatest concentration occurred in one village on the western part of the island where, by my analysis, within a population of 500, one in every twenty-five individuals was deaf. And even there the distribution was not uniform, for in one area of the village during this time period, one out of every four persons was born deaf.

The high rate of deafness on the island brought only occasional comment from island visitors over the years. Because most of the island deaf lived in the more remote areas of the island, few off-islanders were aware of their presence. Vineyarders themselves, used to a sizable deaf population, saw nothing unusual in this, and many assumed that all communities had a similar number of deaf members. Almost nothing exists in the written records to indicate who was or was not deaf, and indeed, only a passing reference made by an older islander directed my attention to the fact that there had been any deaf there at all.

While most of my information on i land deafness has been obtained fro the living oral history of islanders no in their seventies, eighties, and nin ties, part of my genealogical data wa acquired from the only other study this deaf population. I came to know it when an 86-year-old woman I wa interviewing recalled that her mothe had mentioned a "teacher of the dea from Boston" at one time taking a interest in the island deaf. Thi "teacher of the deaf" turned out to b Alexander Graham Bell, who, havin recently invented the telephone turned his attention back to his lifelong interest in deafness research Concerned with the question of heredity as it related to deafness, Bell bega a major research project in the earl 1880s, which was never completed.

Nineteenth-century scholars, without the benefit of Mendel's concept o unit factor inheritance (which only received widespread circulation at th turn of the century, although it ha been published in the 1860s), were at loss to explain why some but not al children of a deaf parent were themselves deaf. Selecting New Englan because of the older and unusuall complete records available, Bell believed that by tracing back the genealogy of every family with two or mor deaf children, he could establish som pattern for the inheritance of deafness He soon found that practically ever family in New England with a histor of deafness was in some way connecte with the early settlers of Martha's Vineyard, but he was unable to account for the fact that a deaf parent di not always have deaf children and s he abandoned the study. Although Bell never published his material, he left dozens of genealogical charts that have proved invaluable for my research—particularly because they corroborate the information I have been able to collect from the oral history of the older islanders.

Since Bell's time, scientists have found, through the construction and analysis of family pedigrees and the use of mathematical models, that congenital deafness may result from several causes: spontaneous mutations involving one or more genes; an already established dominant or recessive inheritance, as Mendel demonstrated; or factors otherwise altering normal development of the ear and its pathways to the brain. Human populations, of course, cannot be studied with the same exactness as a laboratory experi-

# Great ideas last forever

Great inventions have the power to forever change the past.

Victor Hasselblad changed the face of photography forever with the invention of the Hasselblad fully interchangeable camera system.

Never before and never since has there been a camera system to equal the Hasselblad–the *standard* of versatility and quality around the world. That's why Hasselblad is the overwhelming choice of professionals in every area of photography, from fashion to photo-journalism.

At the heart of the Hasselblad System is the 500C/M, with its interchangeable lenses, film magazines, viewfinders and film winder. The possibilities for adapting this basic camera to your own purposes are limitless: 22 different lenses, 7 film magazines, 8 viewfinders, 3 winding devices, 4 focusing screens, and a vast array of specialized accessories.

The Hasselblad 500C/M is easily held in the palm of your hand, yet it gives you the quality advantage of its large $2\frac{1}{4} \times 2\frac{1}{4}$ negative size.

The Hasselblad System has made a profound contribution to photography. It could make a profound difference to you. For a luxurious folder, write to:

ment. However, the appearance of apparently congenitally deaf individuals is far too frequent on Martha's Vineyard to be mere coincidence, and the evidence collected thus far points to a recessive mode of inheritance.

While the genetic nature of a hereditary disorder in small populations is something that both anthropologists and geneticists have studied, there is another question, rarely addressed, that is of equal importance: How does the population of a community in which a hereditary disorder exists adjust to that disorder—particularly one as prominent as deafness? In modern society the emphasis has been on having "handicapped" individuals adapt to the greater society. But the perception of a handicap, with its associated physical and social limitations, is tempered by the community in which it is found. The manner in which the deaf of Martha's Vineyard were treated provides an interesting example of how one community responded to this type of situation. "How," I asked my informants, "were the island deaf able to communicate with you when they could not speak?" "Oh," I was told, "there was no problem at all. You see, everyone here spoke sign language."

From the late seventeenth century to the early years of the twentieth, islanders, particularly those from the western section where the largest number of deaf individuals lived, maintained a bilingual speech community based on spoken English and sign language. What is of particular interest is that the use of sign language played an important role in day-to-day life.

Islanders acquired a knowledge of sign language in childhood. They were usually taught by parents, with further reinforcement coming from the surrounding community, both hearing and deaf. For example, recalling how she learned a particular sign, one elderly woman explained:

> When I was a little girl, I knew many of the signs, and the manual alphabet of course, but I didn't know how to say "Merry Christmas," and I wanted to tell Mr. M. "Merry Christmas." So I asked Mrs. M., his wife. She could hear and she showed me how. And so I wished Mr. M. "Merry Christmas"—and he was just so delighted.

This women then described how she taught her son, now in his late seventies, how to speak the language.

> When my son was perhaps three years old, I taught him to say in sign language "the little cat and dog and baby." This man, who was deaf, he used to like to go down to our little general store and see people come and go. One day when I went down there, I took my son there and I said to him, "Go over and say 'how-do-you-do' to Mr. T.," the deaf man. So he went right over, and then I told him to tell Mr. T. so-and-so—a cat, a dog, and whatever. And wasn't Mr. T. tickled! Oh, he was so pleased to know a little bit of a boy like that was telling him all those things, and so he just taught my son a few more words. That's how he learned. That's how we all learned.

Particularly in the western section of the island, if an immediate member of the family was not deaf, a neighbor, friend, or close relative of a friend was likely to be. Practically all my "up-island" informants above the age of seventy remembered signs, a good indication of the extent to which the language was known and used. In this section, and to a lesser extent in the other villages on the island, sign language formed an integral part of all communications. For example, all informants remembered the deaf participating freely in discussions. One remarked:

> If there were several people present and there was a deaf man or woman in the crowd, he'd take upon himself the discussion of anything, jokes or news or anything like that. They always had a part in it, they were never excluded.

As in all New England communities, gathering around the potbellied stove or on the front porch of what served as a combination general store and post office provided a focal point for stories, news, and gossip. Many of the people I have talked to distinctly remember the deaf members of the community in this situation. As one man recalled:

> We would sit around and wait for the mail to come in and just talk. And the deaf would be there, everyone would be there. And they were part of the crowd, and they were accepted. They were fishermen and farmers and everything else. And they wanted to find out the news just as much as the rest of us. And oftentimes people would tell stories and make signs at the same time so everyone could follow him together. Of course, sometimes, if there were more deaf than hearing there, everyone would speak sign language—just to be polite, you know.

The use of sign was not confined to small group discussions. It also found its way into assembled crowds. For example, one gentleman told me:

> They would come to prayer meetings; most all of them were regular church people, you

Now you can create country fresh air in your home or office. And also watch cigarette smoke, pollen, dust, and other airborne particles disappear from your environment, for less than three cents a week.

All it takes is a small 2½ pound pollution fighter named Ionosphere™. Which, we're convinced, is the most superbly engineered under $200 air ionizer on the market today. Bar none.

The Sharper Image is offering Ionosphere through the mail for just $89.

Ionosphere purifies the air you breathe more efficiently than any fan, exhaust unit or conventional filter system by creating a negative electrical field. One 4-inch unit will ionize up to 250 square feet, or an average 12′ × 20′ room. This negative charge acts on floating particles—even invisible ones—causing them to cluster, fall to the floor or adhere to nearby surfaces. The air becomes pure, feels almost "washed." And Ionosphere is so efficient it requires no fan or other moving parts to disperse these ions.

You probably have experienced this fresh-air feeling before. In nature, negative ions are continually recreated by the dynamic action of the sun, rain and lightning. It's why air smells sweet and invigorating after a thunderstorm, or deep in a forest.

**Power use: approximately 3 watts. Total ion output: $3.8 \times 10^{12}$ ions/sec. Ion density: 10,000 ions/cubic centimeter at 8′. Ozone production: less than .03 ppm. $N_2O$ production: not measurable.**

**Born in academia.**

Major ion research has been conducted at the University of California, Berkeley. Ion Systems, Inc., a private company, was founded to manufacture ionizers to the rigorous standards of this research community. Headed by senior engineer D.A. Gehlke (formerly with the government's Polaris Project), I.S.I. has built almost every hospital ion system in the U.S. Their new portable Ionosphere is constructed with this same level of integrity.

Ionosphere's electronics are both superb and unique. It is the only ionizer that uses "passive multi-stage" circuitry for its noiseless and noninterfering output (many units are known to affect radio reception). Most other units use a "vibration" mechanism, which causes clicks, pops or an annoying high-pitched whine.

The circuitry is embedded in epoxy resin, then encapsulated in an impact-resistant sphere—a solid seamless ball of fine ceramic tile. Hermetically sealed, it is protected from the moisture that inevitably reduces the performance of competitive units. We know of no other company that takes such pains in producing their product.

Other significant differences? For one, a vastly superior ion emitter than you'll find elsewhere. This easily removable element is made from surgical stainless steel bristle, not the more commonly used copper "fuzz" or nickel-plated points. Stainless steel is known for its excellent durability, and this special design guarantees years of consistent ion output. The Ionosphere's emitter will last a lifetime, and cleans easily under hot water.

On other units, you'll also find inexpensive plastic cases. When exposed to a high voltage field, these petrochemicals can be converted to a harmful gas. But Ionosphere's tile case is completely safe.

**More ions aren't necessarily better.**

One 4″ Ionosphere generates approximately 3.8 trillion ions every second. Unlike other units which produce an excessively high output (at the source only), the Ionosphere creates a more *naturally* balanced ion environment. You should also avoid units without stated levels of ozone production (Ionosphere is among the lowest).

**Why do we need ionizers at all?**

Urban life has upset the natural electrical balance of the air. Modern conveniences like heating, air conditioning, telephones and televisions greatly deplete negative ion levels, robbing the air of its natural cleansers. This is also why we feel uncomfortable under fluorescent lights.

Ionsphere restores this balance in just minutes. The air smells good again, even after smoking.

And, as a result of its work, you may need to clean your walls in a year or so. But be glad that same soot was kept out of your lungs.

**Try one, or order a system.**

The $89 Ionosphere comes in white (#946) or black ceramic (#945). Or you may expand your fresh air environment at an $18 savings—with three units at $249; 2 white, one black, (#947). Either way, you can experience the freshest air you've probably ever breathed, without obligation. Ionosphere comes with full instructions and a one year warranty. And if you're not delighted, simply return your order within two weeks for a prompt and courteous refund.

## ORDER NOW TOLL FREE.

> know. They would come when people offered testimonials, and they would get up in front of the audience and stand there and give a whole lecture in sign. No one translated it to the audience because everyone knew what they were saying. And if there was anyone who missed something somewhere, somebody sitting near them would be able to tell them about it.

The deaf were so integral a part of the community that at town meetings up-island, a hearing person would stand at the side of the hall and cue the deaf in sign to let them know what vote was coming up next, thus allowing them to keep right on top of things. The participation of the deaf in all day-to-day work and play situations contrasted with the manner in which those handicapped by deafness were generally treated in the United States during the same time period.

Sign language on the island was not restricted to those occasions when deaf and hearing were together, but was used on a regular basis between the hearing as well. For example, sign language was used on boats to give commands and among fishermen out in open water to discuss their catch. I was told:

> Fishermen, hauling pots outside in the Sound or off Gay Head, when they would be heaven knows how far apart, would discuss how the luck was running—all that sort of thing. These men could talk and hear all right, but it'd be too far to yell.

Indeed, signs were used any place the distance prohibited talking in a normal voice. For example, one man remembered:

> Jim had a shop down on the shore of Tisbury Pond, and his house was a ways away, up on the high land. When Trudy, his wife, wanted to tell Jim something, she'd come to the door, blow a fish horn, and Jim would step outside. He'd say, "Excuse me, Trudy wants me for something"; then she'd make signs to tell him what she needed done.

On those occasions when speaking was out of place, such as in church, school, or at some public gatherings, the hearing communicated through signs. Such stories as the following are common: "Ben and his brother could both talk and hear, but I've seen them sitting across from each other in town meetings or in church and telling each other funny stories in sign language."

Island people frequently maintained social distance and a sense of distinct identity in the presence of tourists by exchanging comments about them in sign language. The occurrence of what linguists call code switching from speech to sign also seems to have been used in certain instances. For example, I was told:

> People would start off a sentence in speaking and then finish it off in sign language, especially if they were saying something dirty. The punch line would often be in sign language. If there was a bunch of guys standing around the general store telling a [dirty] story and a woman walked in, they'd turn away from her and finish the story in sign language.

Perhaps the following anecdote best illustrates the unique way island sign language was integral to all aspects of life:

> My mother was in the New Bedford hospital—had an operation—and father went over in his boat and lived aboard his boat and went to the hospital to see her every night. Now the surgeon, when he left him in her room, said they mustn't speak, father couldn't say a word to her. So he didn't. But they made signs for about half an hour and mother got so worked up, they had to send father out, wouldn't let him stay any longer.

Sign language or rather sign languages—for even within this country there exist a number of distinct languages and dialects—are languages in their own right, systems of communication different from the spoken languages used by hearing members of the same community. It has often been noted that American Sign Language, the sign system commonly used among the deaf in the United States today, is influenced by French Sign Language, introduced to America in 1817. The data from Martha's Vineyard, however, clearly support the hypothesis, made by the linguist James Woodward, that local sign language systems were in use in America long before this. By 1817 (the year the American School for the Deaf was founded in Hartford, Connecticut), deaf individuals on Martha's Vineyard had been actively participating in island society for well over a century. Because they were on an equal footing, both socially and economically, with the hearing members of the community, and because they held town offices, married, raised families, and left legal and personal documents, there must have existed some sort of sign language system that allowed full communication with family, friends, and neighbors.

It may prove difficult to reconstruct the original sign language system used on the island during the seventeenth and eighteenth centuries, but study of this question is currently under way. Whatever the exact nature of the original language, we know that it later grew to acquire many aspects of the more widely used American Sign Language, as increasing numbers of deaf island children were sent to the school in Hartford during the nineteenth century. This combination of the indigenous sign system with the more standardized American Sign Language seems to have produced a sign language that was, in many respects, unique to the island of Martha's Vineyard. The most common remark made by islanders who still remember the language is that they find it very difficult or are completely unable to understand the sign language spoken by off-islanders or the translations for the deaf that are beginning to be seen on television.

The use of sign language as an active system of communication lessened as the number of individuals in the community with hereditary deafness gradually disappeared, the last few dying in the 1940s and early 1950s. This decrease in the number of deaf can be attributed to a shift in marriage patterns that began in the latter part of the nineteenth century, when both hearing and deaf islanders began to marry off-islanders. The introduction of new genes into the once small gene pool has reduced the chance of a reappearance of "island deafness."

As the number of islanders born deaf dwindled, younger generations no longer took an interest in learning sign language, and the older generations rarely had the need to make use of it. Today, very few people are left who can speak the language fluently, although bits and pieces of it can be recalled by several dozen of the oldest islanders. A few signs are still kept alive among those who knew the language and on a few of their fishing boats. As one gentleman, well along in his seventies, told me recently:

> You know, strangely enough, there's still vestiges of that left in the older families around here. Instinctively you make some such movement, and it means something to you, but it doesn't mean anything to the one you're talking to.

*This article presents some of the material Nora Groce has collected in researching her doctoral dissertation in anthropology at Brown University. Her work has been supported, in part, by a grant from the National Institute of Mental Health.*

The Audubon Society Field Guide to North American Wildflowers
The Audubon Society Field Guide to North American Wildflowers

*The 2-book set with snap case is available only through the Club.

These two beautiful books, The Audubon Society Field Guides to North American Wildflowers, Eastern Region and Western Region, are part of a highly praised new series of guides that offer an entirely new, easier, quicker approach to field identification. They arrange wildflower pictures by what you see, instead of by wildflower family. And they show you the flowers in full-color natural-habitat photographs instead of the traditional paintings — so the flowers you see in the books look exactly like the flowers you see in the woods and fields — and you identify them easily by appearance alone. The books are divided into two sections: first you get full-color natural-habitat photographs of 1425 North American wildflowers. Then, in a text that gives you detailed information on each species, the flowers are grouped alphabetically by family, genus and species. Photographs and text are keyed to each other for instant cross reference. The books with their superb photographs, by the country's top nature photographers, are a spectacular showcase of North America's wildflowers.

These books are just the beginning. As a Nature Book Club member, you'll be offered a varied selection of excellent books covering all aspects of nature including animals, birds, plants, fish, minerals, wilderness places, camping, exploration, natural history, science and more — fascinating books, beautiful books — books that you'll turn to again and again, and be proud to own.

**Enjoy substantial savings**

As a Nature Book Club member, you'll be able to buy all Club books at discounts of up to 50% and sometimes even more. Yet in virtually every case, Club books are identical to publishers' editions — same jacket, binding, cover, paper, printing. To become eligible for these bargains, just mail the postpaid card today.

If card is missing, write to:
**NATURE BOOK CLUB**
P.O. Box 2026, Latham, N.Y. 12111

**How your Club membership works.** About every four weeks (14 times a year) you will receive a Club bulletin describing the coming main selection and alternate books also available, all at Club discounts. If you want the main selection only, do nothing. It will be sent automatically. If you don't want the main selection, or want alternate books, or no books, please make sure to indicate your wishes on the Instruction Form and return it to us by the date shown. Club mailings are carefully scheduled to assure you of at least 10 days in which to do this. But in the unlikely event that you don't have 10 days, and you receive an unwanted selection, you may return it at our expense. After receiving your joining shipment, your only obligation is to buy two more regular selections or alternates in the next year. After that, membership may be canceled at any time, by either you or the Club.

**In the months ahead you'll be offered a choice of fine nature books like these typical Club selections at discounts up to 50%**

# The Worm-Asthma Controversy

*Do certain worms cause, protect against, or have no connection with asthma?*

**by Robert S. Desowitz**

Every now and then those two Brahmins of the medical press, the *New England Journal of Medicine* and the British publication the *Lancet*, serve as forums for debates whose resolution affects the health of us all. Most of the arguments have been publicized in the popular press, for example, Does a fat free diet reduce the risk of cardiovascular disease? Do coronary bypass operations benefit the patient more than the surgeon? Another controversy, which has kindled a certain passion in a specialized coterie of followers of the papers and correspondence in these journals and elsewhere, has been whether parasitic worms can cause asthma. The affairs of the heart are well known but the worm-asthma debate is undoubtedly unfamiliar to the general population. Nevertheless, to the two million American asthmatics whose illness costs them an average of 12 to 30 percent of the total family income, any new revelation on the possible causes of their affliction is a breath of life.

If the association between asthma and intestinal worms seems peculiar, the origin of the story is even stranger. The opening chapter was set, not in Nigeria or Nicaragua or some similar tropical country where an intestinal zoo is so common as to be a way of life, but in Niagara Falls, Ontario.

Over the years a doctor there named Tullis noted what seemed to be an extraordinary number of asthmatic cases, 14 percent of all nontubercular patients, seeking medical attention at the Niagara Peninsula Sanatorium. He also found that the usual provocative agents (allergins), such as pollen and house dust mites, did not appear to be the cause of asthma in the majority of those patients. With remarkable intuitiveness, considering Ontario's nontropical geography, Tullis decided to look for intestinal parasites in his patients. After careful examination of fecal specimens, he found the sign of the worm—their characteristic eggs—in 198 of 201 patients with bronchial asthma, while all of his allergy-free controls were "clean."

In 1971, Tullis published his findings in the *New England Journal of Medicine.* The worm-asthma hypothesis was quick to excite the interest of the biomedical community, and other studies were undertaken in an attempt to confirm Tullis's assertion. Confirmation was not forthcoming. From Boston and from the Mayo Clinic in Rochester, Minnesota, investigators failed to find a single worm in any of their asthmatic patients.

The failure to confirm Tullis's findings didn't really dismiss the worm as an allergin. The argument was that while Boston, Massachusetts, and Rochester, Minnesota, might be worm free, Niagara Falls, Ontario, because of its location, was not.

Lake Erie's Canadian bathing beaches are near the Welland Canal, which connects that lake to Lake Ontario. Through this canal passes a lively international maritime commerce manned, in some cases, by tropical seamen and, as stowaways, their intestinal parasites. The sewage discharge from these boats is thought to float to the beaches where the infectious worm eggs are washed ashore. Under these unusual circumstances, the local population is believed to be exposed to that ubiquitous tropical triad of parasites, the roundworm (*Ascaris lumbricoides*), the whipworm (*Trichuris trichiura*), and the hookworm (*Necator americanus* and *Ancylostoma duodenale*).

While the Niagara Falls debate was taking place, Carolyn Coker Huntley, a professor of pediatrics at North Carolina's Bowman Gray School of Medicine, proposed that still another allergin, the dog roundworm, *Toxocara canis,* was of equal, if not greater, importance in provoking asthma. *T. canis* is not sufficiently adapted to complete its development to sexual maturity in a human host. However, when embryonated eggs containing the minute infective larvae are accidentally ingested, as can happen when children grub about in contaminated soil, the larvae hatch and remain for years in the body tissues without maturing further. The infection, known as visceral larval migrans (VLM), is characterized by an enlarged liver and serious lesions of the eye if the larvae invade that organ. Huntley observed that for many of her patients with VLM, the initial symptom was an asthmalike condition, and she suggested that there might be a considerable number of individuals in whom VLM manifests itself mainly as a pulmonary disease. This was an interesting idea, but since it was based solely on clinical insights (it is almost impossible to recover the microscopic larvae within the body), it remained a theory without experimental foundation.

The Huntley hypothesis was of particular interest in Hawaii because the islands have the highest prevalence of asthma in the United States. Could some of the "Waikiki wheeze" be due to parasitic dog worms? Again we were confronted with the problem of making a direct, parasitologic diagnosis, and administering a provocative test dose of worm eggs to asthma patients was clearly unacceptable. However, parasites, whether they be worms, bacteria, or viruses, leave a distinctive spoor, the specific antibody the host produces in response to their intrusion.

# ESCAPADE ECUATORIANA

## TOURS TO SOUTH AMERICA

## The wonders and beauty of all the Americas are yours.

Come to our Andes. Come to our Amazon. Come to our America. We've found the most exciting ways through our mysterious jungles, soaring mountains and fabulous cities. We know where nature is perfectly preserved. And we can show you the most relaxing beaches and exciting nightlife. And hotels and restaurants that are always superb. All through Ecuador. And all through South America.

### Let our Escapade Ecuatoriana tours show you our America:

1. **Ecuador Siempre.** Guayaquil, Cuenca, Quito, Otavalo. 10 days to really get to know Ecuador.
2. **Project Galapagos.** Quito, Galapagos, Otavalo, Cuenca. 15 days in the wilds and wonders.
3. **Jewels of South America.** Quito, Bogotá, Medellin, Cartagena. 12 days in the most beautiful South American cities.
4. **Ecuador & Peru Combo.** Quito, Lima, Cuzco option. 10 days to see two uniquely beautiful countries.

We can help you select just the right South American Escapade Ecuatoriana tour. For expert advice, please see your Travel Agent.

"ANYONE WHO'S THINKING OF SPENDING $24,000 FOR A LUXURY CAR SHOULD TALK TO A PSYCHIATRIST."

*—Dr. John Boston, psychiatrist and Volvo owner, Austin, Texas*

John Boston, a Texas psychiatrist, owns a '73 Volvo.

He bought that Volvo because, as he puts it: "I had admired what Volvo had done in the area of safety. The car seemed well-built. It offered solid European craftsmanship without the inflated price."

We wanted Dr. Boston's opinion of the new Volvo GLE, which has a full assortment of luxury features as standard equipment—and a price tag thousands of dollars below that of the well-known German luxury sedan.

"It's an excellent value. In my opinion, the individual buying this car would have a strong, unsuppressed need to get his or her money's worth. He or she would probably also have a strong enough self-image not to need a blatant status symbol."

When we told him that some people were actually paying five to ten thousand dollars more for a luxury car, Dr. Boston's response was characteristically succinct.

"That's not using your head."

Finally, we asked Dr. Boston if, when he was ready for a new car, he'd consider the Volvo GLE for himself.

"I'd be crazy if I didn't."

**VOLVO**

A car you can believe in.

Using an exquisitely sensitive radioactive technique to measure specific allergy antibodies (given the scientific shorthand designation of IgE), we tested the serum of asthmatic children to determine whether they had antibody specific for dog worms. We expected that a few of the patients in our study would be serologically positive but were startled to find that 45 percent of the group had antibody to these parasites (less than 10 percent of the nonasthmatic control group had "worm" IgE). The immunologic trail not only led to *Toxocara canis* but it revealed that the mosquito-borne parasite of dogs, *Dirofilaria immitis,* was also involved.

*D. immitis,* better known to dog owners as heartworm, is an important cause of debilitating disease in canines. Only recently have we become aware of its potential threat to humans, and the parasite is now considered to be an emerging zoonosis, that is, an infection transmissible from animals to humans. The life cycle of *D. immitis* is typical of filarial, or threadlike, worms. Birthed in dog tissues, the larvae circulate in the blood until picked up by a mosquito in which they mature into infective stage larvae. The infected mosquitoes often bite humans and dogs indiscriminately, inoculating either host with their charge of infective larvae.

Like the dog roundworm, heartworm is incapable of completing its normal life cycle in humans. Instead it migrates to the lungs where it produces a lesion that gives an X-ray picture similar to that of a malignant tumor. That is the extent, so far, of the clinical knowledge of human dirofilariasis, but as with many other "new" diseases, there are undoubtedly several additional manifestations, including allergic hypersensitivity, that have not as yet been identified.

The worm-asthma hypothesis provoked the interest of physicians and biomedical scientists working in the tropics. If the few Niagara Falls worms could cause so much asthma, the allergic potential of the staggering worm burden of the world's warm regions must be enormous. If the theory were true, the globe's girdle between the Tropics of Cancer and Capricorn should be literally wracked by an enormous asthmatic spasm. Asthma had never been considered a significant medical problem in the tropics, where the multitude of regional diseases, many of them life threatening, is so great that a "mere" allergy might have been overlooked.

Contrary to expectation, the epidemiological studies carried out in the tropics indicated that not only were intestinal worm parasites *not* the cause of asthma, they actually *prevented* it. One investigator searched for asthma in The Gambia, the narrow, coastal West African nation that extends inland partway through Senegal. He found that asthma was virtually absent from the rural population but common in city dwellers. The countryside encourages a personal crop of intestinal parasites that come from the soil, while the city environment is relatively protective against these infections. Basing his hypothesis on known immunological phenomena associated with worms, this researcher attributed the absence of asthma in the rural population to the plethora of worms. A group of workers in the Department of Medicine at Ahmadu Bello University in Nigeria came to essentially the same conclusion. Finally, there was an account from a self-infected parasitologist in England. In a letter to the *Lancet,* this specialist wrote that he had had severe hay fever each summer since the age of eight. Then, in the course of one of his experiments, he had need of a regular supply of hookworm larvae and decided to become his own biological supply house. For two years he periodically subjected himself to infective-stage hookworm larvae and during those years he remained completely free from hay fever.

Ultimately, the pro-wormists and anti-wormists were joined by the no-wormists. Investigations carried out in Tanzania and the Gaza Strip failed to show any relationship of intestinal parasites to asthma. Asthma was found to be as prevalent among city dwellers as among rural agriculturists. There were as many asthmatics with worms as nonasthmatics with worms.

So now we have three propositions. One is that parasitic worms cause asthma. Another is that parasitic worms prevent asthma. And the third is that parasitic worms have nothing whatsoever to do with asthma. Which proposal is correct? Probably under certain conditions and in certain individuals any one of the three relationships is possible. The logic of this confusion can best be understood if we first examine the nature of allergy.

Allergy is a kind of immune response. The body's immune system screens and rejects foreign substances, be they parasites, microbial pathogens, or someone else's heart. The system is complex beyond belief, and almost beyond understanding, but essentially it consists of two cooperating agencies: a cell-mediated, or cellular, arm and a humoral, or fluid, arm. The cell-mediated arm is staffed by macrophages—large cells that ingest and digest pathogens and other particulate matter—and by other cells that send chemical signals for the macrophages to assemble where needed. The humoral arm secretes proteins—the antibodies found principally in blood serum—when confronted by a pathogen or other antigenic substance. The antibodies have a specific configuration that allows them to combine with the antigen to render it innocuous.

Without the development of an immune system, animals, including humans, undoubtedly could not have evolved or survived. The ubiquitous attack of a huge array of invading microbes probably would have precluded survival. However, the IgE "allergy antibody" acts somewhat differently from other antibodies and seems to make no adaptive sense. Unlike other classes of immunoglobulins, IgE does not combine directly with the antigen against which it was specifically elaborated. Instead, one end of the antibody molecule fixes to special receptor sites on the surface membranes of certain types of white blood cells and cells present in connective tissue. All these cells are, in a sense, packets of potential dynamite. They manufacture and store histamine and other substances whose action on blood vessels and other tissues is manifested by the symptoms of the allergic state. Fortunately, these substances normally remain within their cellular storehouses. (In an earlier article, "Harmonious Parasites," *Natural History,* September 1977, I described how they are released when the cell-fixed IgE molecules become bridged at their exposed ends by the allergin.)

That is the how of allergy. The why is still not completely understood, although both genetic predisposition and the nature of the provoking allergin play a role. Five classes of immunoglobulins have been recognized—IgG, IgM, IgA, IgE, and IgD. When an individual is exposed to an antigen, a group of specialized cells, the plasma cells, are switched on, begin to proliferate, and then manufacture and se-

# ¡Speak Spanish like a diplomat!

What sort of people need to learn a foreign language as quickly and effectively as possible? *Foreign Service personnel*, that's who. Members of America's diplomatic corps are assigned to U.S. embassies abroad, where they must be able to converse fluently in every situation.

Now *you* can learn to speak Spanish just as these diplomatic personnel do—with the Foreign Service Institute's Programmatic Spanish Course.

The U.S. Department of State has spent tens of thousands of dollars developing this course. It's by far the most effective way to learn Spanish at your own convenience and at your own pace.

The Programmatic Spanish Course consists of a series of tape cassettes and an accompanying textbook. You simply follow the spoken and written instructions, listening and repeating. By the end of the course, you'll find yourself learning and speaking entirely in Spanish!

**This course turns your cassette player into a "teaching machine."** With its unique "programmatic" learning method, you set your own pace—testing yourself, correcting errors, reinforcing accurate responses.

**AUDIO-FORUM®**

The FSI's Programmatic Spanish Course comes in two volumes. You may order one or both courses:

- ☐ Volume I, Basic. (11 cassettes, 16 hours), instructor's manual and 464-page text, $115
- ☐ Volume II, Advanced. (8 cassettes, 11½ hours), instructor's manual and 614 page text, $98 (New York residents add sales tax.)

Your cassettes are shipped to you in handsome library binders.

**TO ORDER, JUST CLIP THIS AD and mail with your name and address, and a check or money order.** Or, charge to your credit card (American Express, VISA, Master Charge, Diners Club) by enclosing card number, expiration date, and your signature.

**The Foreign Service Institute's Spanish course is unconditionally guaranteed.** Try it for three weeks. If you're not convinced it's the fastest, easiest, most painless way to learn Spanish, return it and we'll refund every penny you paid! Order today!

Many other FSI language courses also available. Write us.

At your Bushnell dealer or write Bushnell Optical Co., Dept. NH58, 2828 East Foothill Blvd., Pasadena, Ca 91107.

crete one of the five classes of antibody that will specifically combine with the antigen. In most humans this will be the IgM and IgG classes but some individuals may switch on other classes. In allergic individuals the genetically directed response is, primarily, to switch on a clone of IgE-secreting plasma cells. Thus, allergy is an inherited factor but only in the broad sense. For example, a person who is allergic to fish will not pass on that particular allergy but will pass on the tendency to become allergic. The allergin that plagues the parent may be very different from the one that plagues the child.

The chemical and structural acrobatics that turn an antigen into an allergin have not, as yet, been identified. We know that certain antigens are more likely to switch on an IgE response than other antigens. Pollens and house dust mites, for example, are more allergenic than bacteria or viruses. But of all the allergins, the parasitic worms are the most powerful in stimulating IgE production.

In normal individuals, the serum IgE concentration is less than 200 units per milliliter; in hypersensitive individuals with pollen allergy it is some 400 to 600 units; in those with worm infections it usually ranges from 1,000 to 5,000 units. Some of this IgE is specific antibody for the worm, some of it seems to be nonspecific "rubbish" antibody, and some of it may be directed against completely different allergins. Experiments have shown that worm infections can potentiate IgE antibody responses against completely unrelated allergins. If these observations hold true for humans, an individual with worms could be more hypersensitive to pollen, for example, than an individual without worms. To make matters even more confusing, other experiments have shown that some parasitic infections suppress immune responses to unrelated antigens. In that case, our wormy individual would be less sensitive to pollen than his "clean" counterpart.

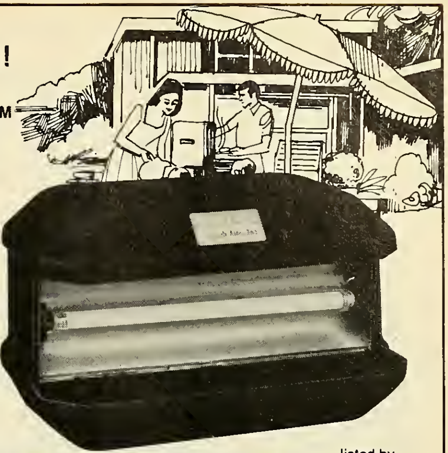
Within this maze of conflicting experimental observations may lie the answer to the worm-asthma controversy. It is probably a matter of degree. A few worms in "immunologic virgins," such as the patients in Niagara Falls, may stimulate production of specific IgE antibody to the worms and/or potentiate IgE elaboration to other allergins. A large number of worms and constant reinfection, such as occurs under the unsanitary conditions of much of the world's warm and wormy regions, would probably stimulate nonspecific, as well as specific, IgE and also suppress the immune responses to other antigens. The large amount of nonspecific rubbish antibody in those with worm infections would act as "blocking" antibody, preventing the release of histamine and inhibiting allergic asthma. Worm loads of an intermediate magnitude might have no effect on the inhibition or production of asthma and the other manifestations of allergy. Other factors, such as the kind of worms endemic to a particular region and the immunogenetic character of the population, may also be imposed upon this speculative scenario.

I said earlier that the immune response that causes the allergic state made no adaptive sense. What benefit can be gained from hay fever, food allergy, or asthma? But unless Darwin is to be denied, at some time in mammalian evolutionary development the allergic reaction must have had selective advantage. It may have begun, for instance, to give the intestinal worm an "asthmatic attack."

All mammalian species have unwelcome intestinal worms embedded in the lining of their intestines, and it has now been shown that IgE plays an important role in getting rid of them. The IgE becomes fixed to most cells in the intestinal connective tissues. These cells localized about the worm discharge their pockets of histamine when the parasite's antigens, probably their metabolic products, couple to the antibody. The histamine and other pharmacologically active substances act on the parasite to give it an "allergic spasm" that causes it to vacate its site and be swept away in the feces.

Thus when that first mutant plasma cell tentatively produced an antibody molecule that became fixed to host target cells, it may have served man's distant ancestors as an agent to destroy or expel worms. Unfortunately, what may have started as a good thing became a disaster, and eventually, there developed an IgE plasma cell population that recognized and responded to all the allergins that now bedevil us. However, relief from allergy may yet be found to reside in the creature that could well have started it all—the worm.

*Robert S. Desowitz teaches tropical medicine at the University of Hawaii.*



**The end of pesty flying insects!**

**Patio Pal™ kills bugs from a third of an acre without chemicals, odor or electrocution!**

**Totally safe for children and pets—complies with standards of the ENVIRONMENTAL PROTECTION AGENCY and the USDA**

listed by UL

U.S. Pat. No. 3336694, 3753040, 3755666

**Bugs have a "fatal attraction" to Patio Pal's "black light blue"**

Deep in the heart of mosquito country in Florida, USDA scientists discovered a lure that flying insects find irresistible. They call it "black light blue". This remarkable light actually attracts hundreds of different types of flying insects from up to a third of an acre.

Using this important scientific discovery, Fresh Aire, Inc. created the Patio Pal, one of the most amazingly effective, simple and safe bug killers ever! Inexpensive and easy to install, Patio Pal makes it possible for you and your family to really enjoy warm weather without those pesty people-biters!

**Here's how it works...**

Just plug Patio Pal in using ordinary household current, place it about 25 feet from where you're relaxing, and it immediately begins to draw bugs away from you. Mosquitoes, gnats, flies, even beetles and wasps are drawn like a magnet to Patio Pal's "black light blue". Once they're up close, a downdraft created by a powerful hidden fan, sweeps them inside and into a pan of water where they're quickly drowned. No chemicals, no smelly citronella candles, no mess, and best of all, no pesty bugs!!

**Stay outside as late as you like!**

Imagine! All day long and late into the night, you and your friends and family can sunbathe, picnic, barbecue, play tennis or cards, do as you please without bothersome bugs buzzing around. Even after a summer rainstorm, bugs won't bother you with Patio Pal around!

**Ecologically safe**

Yes, Patio Pal's no-chemical operation means there are no pollutants to harm your vegetable or flower garden. No worry about kids or pets. Patio Pal works on bugs only. What's more, you just empty the pan of water into the garden or grass about once a week and let the birds snack on the insects! Truly, the safest, most effective bug killer ever. Listed by Underwriters Laboratory.

**Built to last for years**

Yes, Patio Pal is quality constructed to be virtually impervious to bad weather and wear. And what a great bargain at just $49.95. That's up to $100 less than many electric bug killers.

**Prove it to yourself without risk**

Still a trifle skeptical? No problem! We're so certain that you'll be 100% delighted with Patio Pal's fatal effect on bugs, that we're inviting you to test it in your own backyard for 15 days. If not thoroughly impressed, you may return it for a prompt refund.

Order Patio Pal today and make this summer one of the most enjoyable ever—without those pesty buzzing, biting bugs!

*An extraterrestrial object may have brought mass extinction on the earth 65 million years ago*

**by Stephen Jay Gould**

The ten plagues of Moses are the archetypal disasters of Western thought. I am therefore not surprised that popular explanations for major catastrophes in the history of life have tended to follow their scenarios in spirit. The most famous (although not the most profound) mass extinction occurred some sixty-five million years ago at the close of the Cretaceous period. All surviving dinosaurs died, as did their giant cousins in the air (pterosaurs) and in the seas (ichthyosaurs, plesiosaurs, mosasaurs). The oceanic plankton virtually disappeared with dramatic suddenness at a boundary that geologists call the plankton line. Several major groups of marine invertebrates perished, including all ammonites and the curious rudistid clams, which looked like corals and formed reefs.

Evidence for the cause of this great dying is so sparse that speculation receives free rein (and reign). The primal scenarios of Moses force themselves upon us. Theories of pandemics run wild recall the murrain that killed Pharaoh's cattle and the boils "breaking forth upon man, and upon beast." Poisoning of the oceans by copper washed in from the land or by a lens of fresh water spreading out from a fractured arctic lake reminds us of the Nile turned to blood—"and the fish that were in the river died; and the river stank. . . ." Dramatic change of climate conjures up the great hailstorm that fell "upon man, and upon beast, and upon every herb of the field. . . ." Voracious predators and parasitic pestilences have their counterpart in the successive deluges of frogs, lice, flies, and locusts that Pharaoh endured. Even the slaying of the children recalls the common (if rather silly) speculation about primitive mammals happily munching on dinosaur eggs. The only Mosaic plague that has not been well represented among the catalog of late Cretaceous disasters is the great darkness that blanketed Egypt for three days—"even darkness which might be felt."

I am happy to report that this serious omission has now been rectified. I am even more delighted to report that this latest entry has a basis in evidence of an entirely new sort. It has made legitimate, for the first time, a large class of explanations heretofore characterized by perfect plausibility in theory combined with utter lack of confirming evidence—extraterrestrial events. Would you believe an asteroid so big that it hit the earth and threw up a dust cloud thick enough to block photosynthesis entirely for a decade? Pharaoh almost tossed in the towel after a mere three days. But let me bypass the asteroid for a few paragraphs to discuss some ground rules and principles about mass extinction.

The major theories of mass extinction can be divided into two groups according to their stance on each of two issues: *source* (within or outside the earth) and *rate* (truly sudden or only relatively rapid). The earth itself is a source for some proposed causes, either by such physical mechanisms as changing climates engendered by shifting continents, or such biological factors as disease, competition, and collapse of food chains. Extraterrestrial hypotheses have ranged from variation in solar output, to cosmic radiation from nearby supernovae, to impacts of various bodies. Some notions of rate posit not merely a relatively rapid blip in the vastness of time but true cataclysms, disasters on the short scale of a human life—extraterrestrial impact theories, for example. Other determinants of mass extinction would be too slow to note during a human lifetime, but do their work in thousands or even millions of years, against a backdrop of billions. Most of these implicate changes of climate, including drops in sea level and the growth of glaciers.

Geologists, like all folks, have their prejudices. They prefer causes emanating from their own domain, the earth. Since Lyell's day they have been trained to view major change as the accumulation of small inputs based on processes that can be observed in the relatively calm geologic present. These preferences have combined to give cataclysmic extraterrestrial theories a poor shake. Yet I think that few geologists would deem it inherently impossible, or even unlikely, that the earth might have suffered grievous cosmic insults at very infrequent intervals during its vast history.

But there is another reason, better than traditional prejudice, for the low esteem of extraterrestrial catastrophes. Geologists have not known, even in principle, any way to obtain direct evidence for them. What direct sign would a supernova or pronounced

## Take Van Nostrand's Scientific Encyclopedia or any one of four Libraries for only $2.97 as a member of the Natural Science Book Club

if you will join now for a trial period and take only 3 more books—at handsome discounts—over the next 12 months.

### 4 Good Reasons to Join

**1. The Finest Books.** Of the hundreds of science books published each year, only the very finest are selected and offered. Moreover, our books are always of equal quality to publishers' editions, *never* economy editions.

**2. Big Savings.** In addition to getting either Van Nostrand's Scientific Encyclopedia or any one of the four libraries for only $2.97 when you join, you keep saving substantially—up to 30% and occasionally even more. (For example, your total savings as a trial member—including this introductory offer—can easily be over 50%.)

**3. Bonus Books.** Also, you will immediately become eligible to participate in our Bonus Book Plan, with savings of at least 70% off the publishers' prices on any book offered in the Club.

**4. Convenient Service.** At 3-4 week intervals (16 times per year) you will receive the Book Club News, describing the coming Main Selection and Alternate Selections, together with a dated reply card. If you want the Main Selection, do nothing and it will be sent to you automatically. If you prefer another selection, or no book at all, simply indicate your choice on the card, and return it by the date specified. You will have at least 10 days to decide. If, because of late mail delivery of the News you should receive a book you do not want, we guarantee return postage.

Please accept my application for trial membership and send me either Van Nostrand's Scientific Encyclopedia or any one of the four libraries, billing me only $2.97. I agree to purchase at least three additional Selections or Alternates during the first 12 months I am a member. Savings range up to 30% and occasionally even more. My membership is cancelable any time after I buy these three books. A shipping and handling charge is added to all shipments.

Check which one you want:
- ☐ Van Nostrand's Scientific Encyclopedia (00470-3)
- ☐ Archaeology Library (10100)
- ☐ Library of Ancient Mysteries (10105)
- ☐ Nature Library (10110)
- ☐ Basic Astronomy Library—A (35558)

**No-Risk Guarantee:** If you are not satisfied—for any reason—you may return your introductory books within 10 days and your membership will be canceled and you will owe nothing.

Van Nostrand's SCIENTIFIC ENCYCLOPEDIA
Fifth Edition

## 1.

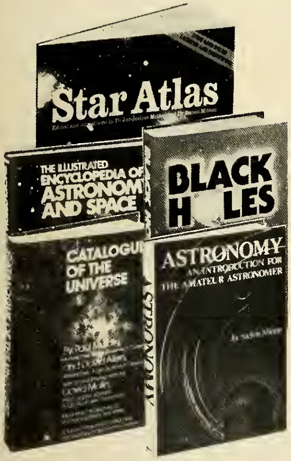
## Van Nostrand's Scientific Encyclopedia

*Edited by Douglas M. Considine.* Nearly 200 experts have contributed to the thoroughly revised and expanded Fifth Edition of the most authoritative single-volume source of scientific information ever assembled. Over 2,500 illustrations.
Publisher's Price $69.50

MYSTERIES OF THE PAST
The mystery of the Pyramids
MYSTERIES OF THE MEXICAN PYRAMIDS

## 2. Library of Ancient Mysteries

Stunningly beautiful set consisting of three 8½" × 11" volumes overflowing with magnificent color photographs consists of **Mysteries of the Past**—a captivating investigation of great historical riddles; **The Mystery of the Pyramids**—a fascinating overview of Egyptian civilization; and **Mysteries of the Mexican Pyramids.**
Publishers' Price $74.90



Star Atlas
THE ILLUSTRATED ENCYCLOPEDIA OF ASTRONOMY AND SPACE
BLACK HOLES
CATALOGUE OF THE UNIVERSE
ASTRONOMY AN INTRODUCTION FOR THE AMATEUR ASTRONOMER

## 3. Basic Astronomy Library

A carefully-selected set of five books that will provide you with a basic, well-rounded astronomy library. Includes: **The Illustrated Encyclopedia of Astronomy and Space, Astronomy: An Introduction for the Amateur Astronomer, Star Atlas, Black Holes** and **Catalog of the Universe.** Publishers' Price $61.75

Fossils of All Ages
fieldbook of natural history
ATLAS OF MAN

## 4. Nature Library

Sumptuously illustrated three-volume set consists of **Fieldbook of Natural History**—a huge field guide to plants, animals and minerals; **Atlas of Man**—a 9" × 12" volume filled with over 450 photographs and maps; and **Fossils of All Ages**—an oversized word-and-picture masterpiece revealing the history of fossils and how they are formed. Publishers' Price $79.95

GRAHAME CLARK
World prehistory in new perspective
MEGALITHS and their Mysteries
AN INTRODUCTION TO ANCIENT EGYPT

## 5. Archaeology Library

Three-volume set consisting of **World Prehistory in New Perspective**—a global survey of all ancient civilizations; **An Introduction to Ancient Egypt**—a lavishly illustrated look at its history, religion and culture; and **Megaliths and Their Mysteries**—a detailed exploration of the standing stones of old Europe.
Publishers' Price $62.90

As a member, you'll be kept informed of the most interesting, most important science books being published. You'll get to choose from a dazzling array of books—from fascinating accounts of the discovery of lost civilizations to speculations on the origin of our universe, from lavishly-illustrated, authoritatively written books on the world of nature to stimulating books on where man came from and where he is going—all at handsome discounts. Join now and see for yourself.

If the reply card has been removed, please write to **Natural Science Book Club,** Dept. 4-AC9, Riverside, N.J. 08370 to obtain membership information and an application.

variation in solar intensity impose upon the earth? Indeed, the traditional argument for cosmic ray zapping by supernovae relies upon total lack of evidence—the fact of mass extinction accompanied by no recognized geologic agent that might have caused it! Thus, many geologists, including myself, have long found themselves in the uncomfortable position of viewing extraterrestrial catastrophes as inherently plausible but rooting strongly against them because we knew no way of obtaining evidence for such catastrophes even if they had occurred. The asteroidal theory has changed all that.

The facts of the Cretaceous extinction exert constraints upon the types of theories we may propose to explain them. We know, for example, that the extinctions occurred throughout the world and in all major environments—land, air, and sea. This alone virtually invalidates the entire panoply of popular theories that would attribute the extinction of dinosaurs to a cause related only to their supposed lumbering inefficiency—mammals eating their eggs, flowering plants pumping too much oxygen into the atmosphere, hyperpituitarism arising from large size and leading to sterility. Any harebrained idea can win notoriety in a context of such public fascination. Someone once proposed in all seriousness that male dinosaurs simply became too heavy to mount their partners for sexual intercourse, although I could never figure why little *Velociraptor* became extinct along with its giant cousins (not to mention what the giant brontosaurs were doing during the 100 million years or so of their success). The primary fact of dinosaur extinction is its timing as part of a global mass dying. We need a general theory, not a set of facile speculations for single groups.

We also know that the Cretaceous extinction included some aspects of geologically sudden death and others of more lingering demise. For some groups, the final phase of the Cretaceous seems to have acted more as a *coup de grâce* than an exterminating angel. Dinosaurs and ammonites had been in decline for millions of years. The dinosaur fauna of the latest Cretaceous did not include one of everything around a waterhole (as the multicolor chart on my kid's wall suggests), but a sharply reduced assemblage consisting largely of *Tyrannosaurus, Triceratops*, and a few smaller creatures. We can also correlate these slower declines with some geologic events often implicated in extinctions (but please remember that correlation need not imply cause). Sea level declined steadily throughout the late Cretaceous; the continuous seaway that had split North America in two, running from Alaska to the Gulf of Mexico, withdrew gradually in both directions. As sea level dropped and continents grew in height and extent, temperatures began a general decline that continued throughout the next seventy million years, culminating in our recent (and still uncompleted) cycle of glacial ages.

Falling sea level has accompanied nearly every mass extinction that the earth has suffered; this correlation is about the only aspect of mass extinction that evokes general agreement among geologists. Its negative effect upon biological diversity also makes sense—for falling seas drained the extensive but shallow continental shelves, thereby removing a large chunk of living space from the domain of shallow-water invertebrates, the dominant fauna of our fossil record. Harsher conditions then spread across the land as the increasingly erratic and generally colder weather of a more "continental" earth prevailed. No dinosaur may ever have eaten an ammonite (although the giant mosasaurs, overgrown varanid lizards, did), but the coordinated decline of both groups may be causally related to dropping sea levels.
